## ACKNOWLEDGEMENTS

Start with the name of Allah Almighty who holds and guides us in darkness. I owe to start with the praise of Allah Almighty as I know I am nothing without His help.

It is my pleasure to acknowledge different people who have been contributed a lot to my thesis. Firstly, I am incredibly thankful to my supervisor Prof. Dr. Sarmad Hussain for inspiring me with the idea for this project and of course for supervising me. I am very lucky to have a supervisor like him. I would like to express my gratitude for his patience, encouragement and guidance during my research. He is an inspiration for me to enter into the challenging field of research. I am very obliged and thankful to him for responding my queries each and every time during this work.

I am very grateful to the former chairperson Mr. Rao Jalil and the present chairperson Dr. Shaban of Department of English Language and Literature, for their co-operation and guidance. I am thankful to all my teachers who helped me in my queries. Specially, I would like to thank Prof. Dr. Abdul Hameed, dean of School of Social Sciences and Humanities who has guided me in analyzing the data statistically well. I am also grateful to Ms. Sana and Sr. Asad who always encouraged and motivated me. I would like to say special thanks to my friends Afsheen Razaqat Ali and Saba Noman for guiding me in the technical problems. I am grateful to all my friends and colleagues who helped me in my queries.

Finally, I am indebted to my beloved parents and my family from my core of the heart. Without their affectionate love, continuous encouragement and support, it would be very difficult for me to complete my degree and especially this research work.

## ABSTRACT

Urdu is a lingua franca, an official language (Mahmood, 2004) and the mother tongue of only 7.5% population in Pakistan (Zia, 2011). The present study deals with an acoustic phonetic analysis which is conducted for finding out the accent variation in Pakistani Urdu. As, we know, Pakistan is a multilingual country therefore the purpose of the research is to analyze the influence of the other languages on Urdu. This research is based on quantitative methodology. The list of the 139 district names has been used as a corpus. The recording of the utterances by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages have been collected by developing a system for online data collection. 30 Volunteers of each language have been enrolled to provide recordings for speech corpus. The corner vowels from the utterances have been evaluated by comparing them with the acoustic properties. Accent differences are acoustic manifestations of differences in duration, pitch, intonation pattern and of course the difference in phonetic transcription (Yan & Vaseghi, 2002). As this is the first step in the work of an acoustic phonetic study of Urdu accents therefore only variations of vowels have been identified by measuring the formant frequencies manually in PRAAT software. The preliminary analysis of first and second formant frequencies showed the differences in the characteristics of vowels. This research has verified that the formant frequencies of the vowels (uttered by the speakers of six major languages) show differences and variations across phonetic context. This is due to the fact that Urdu is the second or third language for Pakistani speakers (Rehman, 2002). It has also verified that some utterances are showing more similar values of formant frequencies (of the speakers' utterances) than the others e.g. the formant frequencies in the utterances of Urdu and Punjabi speakers while

the other showing more variant and dissimilar formant tendencies as in the case of Urdu, Punjabi and Sindhi language speakers' utterances.

## CHAPTER 1

### INTRODUCTION

Pakistan is a multilingual country as people could communicate and understand more than two languages but the majorly spoken languages are only six those are Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. Among the different linguists, there is a controversy in deciding the total number of languages in Pakistan. The difference in the number of spoken languages occurs because of the confusion of languages as dialects or independent languages as Rehman (2002) said that there are 59 spoken languages in Pakistan whereas according to Ethnologue, there are 72 spoken languages and most of these languages are belonging to Indo-Aryan, Indo-Iranian, Indo-European, and Turkic language families (Gordon, 2005).

Even though, Urdu is an official language of Pakistan (Mahmood, 2004) but the accent, lexicon and prosody vary across geographical areas. In Pakistan, there are six prominent accents of Urdu, based on the native languages of the speakers; namely Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki (Rehman, 2002). Accent variation is really based on the duration, pitch, amplitude and the intonation patterns of phonemes (Yan et al., 2005; Reetz & Jongman, 2008). The term “accent” means a pattern of pronunciation used by a speaker to which he or she belongs. Linguistically, accent variation does not only lie in phonetic characteristics but also in prosody (Cole, 2012). Accent is also one of the main factors that impacts Automatic Speech Recognition (ASR) system (Benzeghiba, et al., 2006).

This research is a first step in analyzing the accent variation in Pakistani Urdu language. Therefore, in this study, only vowels have been analyzed acoustically by measuring formant frequencies; F1, F2. The formant frequencies greatly contribute to the better understanding of spoken languages and their accents. Formant frequencies of vowels have been analyzed in PRAAT and mean values have been calculated for each vowel. Then, these mean values have been compared pair wise and group wise. This analysis has verified that multilingualism is the major cause of accent variation in Urdu language and also has proved that Pakistani Urdu has six major accents.

### **1.1. Scope of the Study**

The acoustic phonetic study of vowels is beneficial for Human Computer Interaction (HCI) used for industrial and social applications i.e. applications for telephonic communication, banking, military, health care and education. However, significant development and research have been achieved for English language. Hence, the present study focuses on the progress and development of Urdu language, especially in the area of acoustic phonetics that will investigate the physical properties of sound and also will prove beneficial for the Automatic Speech Recognition (ASR) system.

### **1.2. Statement of the Problem**

A lot of work has been done in Urdu literature and grammar. But there is no major work done on the acoustic properties of the different accents of Urdu. Pakistani speakers use Urdu for mutual communication but they may have different first and second languages. Accents of the different native languages affect the accent of Urdu as

well. This acoustic analysis has been conducted for finding the similarities and differences among major accents of Urdu.

### **1.3. Motivation and Goal of the Study**

In the constitution of 1956, Urdu has been declared as a national language (Rehman D. T., 2006) and is also a lingua franca in Pakistan. For that reason, it is widely used, both formally and informally; in communication, education, literature, business, media and governance.

Urdu is also the first language of only 7.5% population in Pakistan: the reason is, in different districts of Pakistan, people have different mother languages but Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki have comparatively larger population than other languages and all these languages may or may not be intelligible among people in different geographical areas (Zia, 2011) as it is evidently clear that each language has region specific prosodic and lexical features (Gordon, 2005).

But Urdu is the second or third language for almost all Pakistani speakers therefore, it has acquired Pakistani flavor by absorbing Punjabi, Sindhi, Balochi, Pashto and Saraiki languages in terms of accents and vocabulary so there are six major accents of Urdu in Pakistan (Rehman T. , 2002).

The present study will also proved beneficial for the curriculum development of Urdu in Pakistan. And the received phonetic inventory could be added in Urdu grammar and composition books for the development and progress of the spoken Urdu language in Pakistan. The phonetic inventory will also prove beneficial for teachers' training. The

trained teachers will ultimately play their role in the progress and development of Urdu language among young learners.

#### **1.4. Research Question**

This study deals with the acoustic phonetic analysis of the vowels. It presents the answer to the question:

Whether all the six major languages of Pakistan affect Urdu language or not?

#### **1.5. Delimitations**

This proposed study only deals with the segmental features, not with the supra-segmental features of the corner vowels.

## CHAPTER 2

### LITERATURE REVIEW

The research is conducted for finding out the accent variations in Urdu, the national language of Pakistan. The aim of this project is the production of *Urdu Phonological Atlas* which will be explained the present condition of the phonological system of accents in Pakistan. Medium of mobile or telephone had been used for the collection of data. All the native speakers who were the members of the local speech community were selected from different universities of Pakistan for the collection of Urdu speech data. The speech data had been analyzed acoustically in PRAAT. This study will be the first research on the acoustic phonetic analysis of Urdu accents in Pakistan. It presents the answer of the question:

1. What are the majorly spoken accents of Urdu language in Pakistan?

This research provides a first overview of the accent variations; affecting Urdu language in Pakistan which is the principal aim of this project. The current state of Urdu is the result of the active process of changes and diversifications due to the affect of other major neighboring languages which we have been tracing. As the focus of the present research is the comparison of the utterances of Urdu speakers with the utterances of Punjabi, Sindhi, Balochi, Pashto and Saraiki language speakers. This study has only dealt with the phonemic information of sounds therefore the orthography of these languages would not be discussed here. As, a spoken language consists of successions of sounds emitted by the speech organs along with certain attributes: each speech sound belongs

either to the vowel or the consonant. It was also discovered that there are different sounds which are neither vowels nor consonants. Thus, may be termed as semi-vowels /w/, /r/, /j/ and laterals /l/ by showing the mixed properties of vowels and consonants (Roach, 2009).

## Important Terms

Articulatory phonetics, auditory phonetics, acoustic phonetics, formant features (F1, F2 values), PRAAT, spectrogram, phonetic inventory, accents and multilingualism

### 2.1. Articulatory Phonetics

Articulatory phonetics deals with the movement of different parts of vocal tract for the speech production (Universitat Bielefeld, 2010). Articulatory phonetics also tells us about the places and manners of articulation for different phonemes. The articulation of speech is based on the following three processes;

- a) the airstream process,
- b) the phonation process,
- c) the oro-nasal process

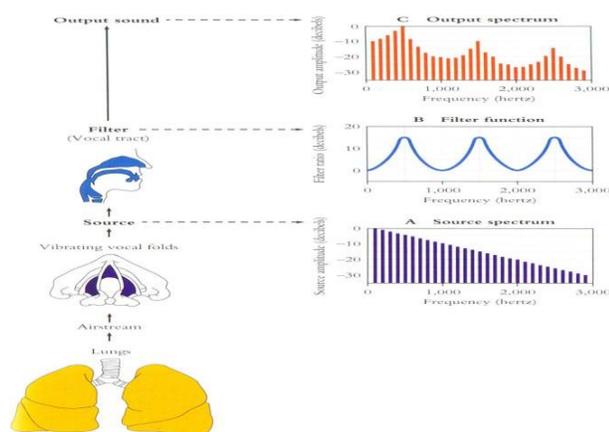

Figure 1: Process of Articulation<sup>1</sup>

<sup>1</sup> Retrieved 12-8-2013: [http://www.uni-bielefeld.de/\(en\)/lili/personen/dschlangen/publications.html](http://www.uni-bielefeld.de/(en)/lili/personen/dschlangen/publications.html)

## 2.2. Auditory Phonetics

Auditory phonetics<sup>2</sup> deals with the perception of sounds or the way in which sounds are being heard and perceived. If articulatory phonetics deals with the speaker than auditory phonetics deals with the listener.

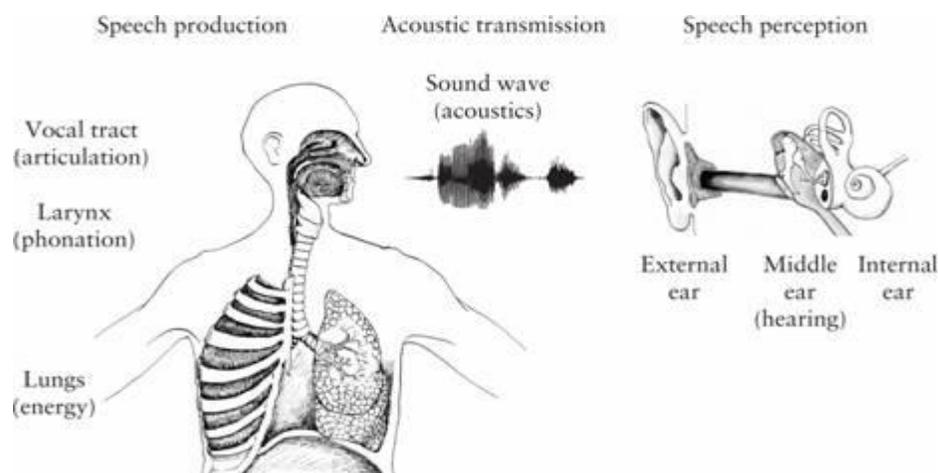

Figure 2: Production and Perception of Speech

It directly deals with the physiology and anatomy but directly related with the utterance of speech. Anatomy and physiology are distinct processes but are closely interrelated with each other. One is the audition or perception of the sounds by auditory apparatus; sending it to brain by converting it into neural signals and the other deals with the analysis of these neural signals in the brain by decoding and understanding of the verbal information given by the speaker. The first anatomical organ is the *ear* of the listener and the last is the *brain* of the listener so we can say that the speech production is a *chain process* which starts from the speaker's brain and ultimately ends to the listener's brain (Universitat Bielefeld, 2010).

<sup>2</sup> Retrieved 12-8-2013: <http://www.ebooks.unibuc.ro/filologie/mateescu/pdf/23.pdf>

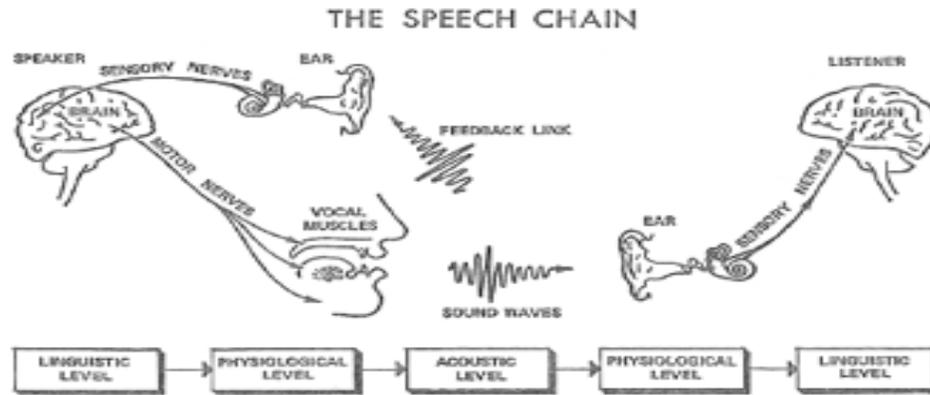

Figure 3: The Speech Chain, speaker's mind to listener's mind<sup>3</sup>

### 2.3. Acoustic Phonetics

The acoustic phonetics deals with the physical properties (pitch, loudness, amplitude, quality and spectrographic properties) of the sound waves during the speech production process (Universitat Bielefeld, 2010).

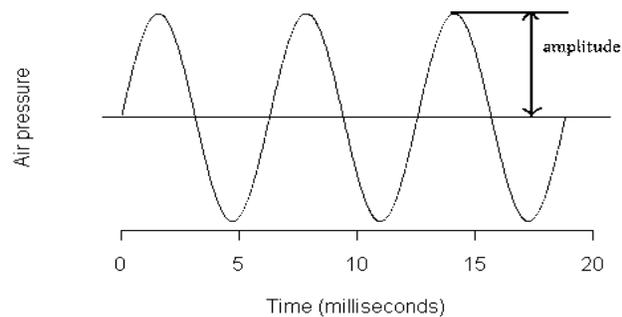

Figure 4: Physical Properties of Sound Wave<sup>4</sup>

### 2.4. PRAAT

PRAAT is a computerized program used to analyze the sound waves by playing, annotating and analyzing the sound objects in terms of acoustic properties i.e. frequency, pitch, intensity, etc. Formants are shown in red dotted lines in spectrogram of PRAAT.

<sup>3</sup> Retrieved 12-8-2013: [http://www.uni-bielefeld.de/\(en\)/lili/personen/dschlangen/publications.html](http://www.uni-bielefeld.de/(en)/lili/personen/dschlangen/publications.html)

<sup>4</sup> Retrieved 12-8-2013: [http://www.uni-bielefeld.de/\(en\)/lili/personen/dschlangen/publications.html](http://www.uni-bielefeld.de/(en)/lili/personen/dschlangen/publications.html)

Different tiers are used to segment the speech waveform for further analyses (Universitat Bielefeld, 2010).

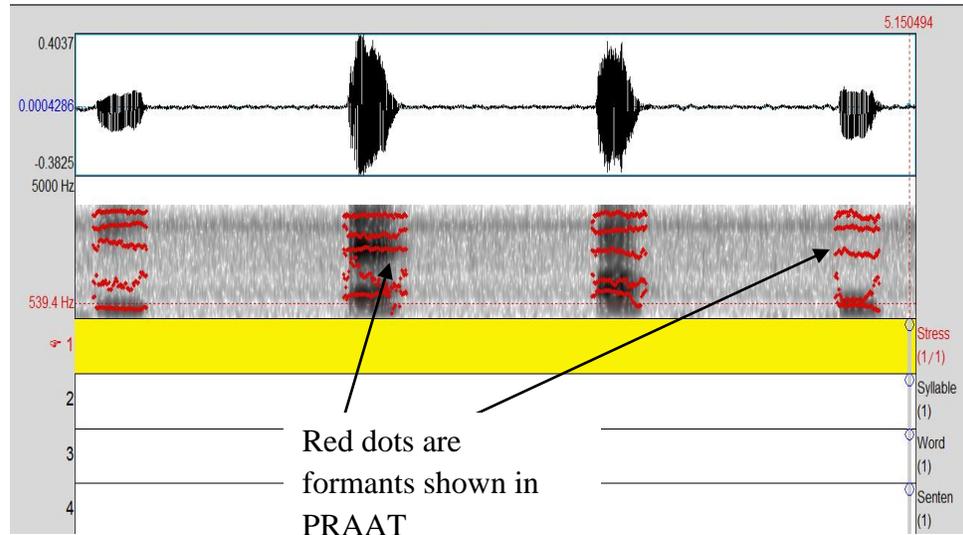

Figure 5: Formants Analysis in PRAAT

## 2.5. Spectrogram

Spectrogram is the graphical representation of sound waves by explaining their component frequencies. It also shows three dimensional information i.e. frequency (vertical axis), time (horizontal axis) and acoustic energy means the formant frequencies; the dark shading bands on spectrogram (Universitat Bielefeld, 2010).

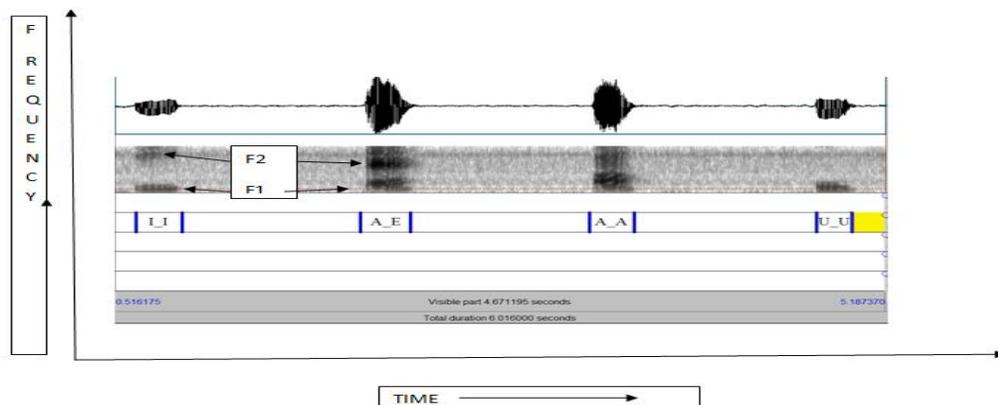

Figure 6: Three Dimensional Spectrograms

### 2.5.1. Formant Frequencies

Formants are produced with the vibrations of air stream in the vocal tract, and these vibrations may or may not be harmonic; in other words, formants are the concentration of the acoustic energy and groups of overtones corresponding to a resonating frequency of the air in the vocal tract and also are the energy peaks which determine the quality of sound waves especially vowels therefore, vowels are characterized by using three formants; F1, F2 and F3 (Karamat, 2012: Universitat Bielefeld, 2010).

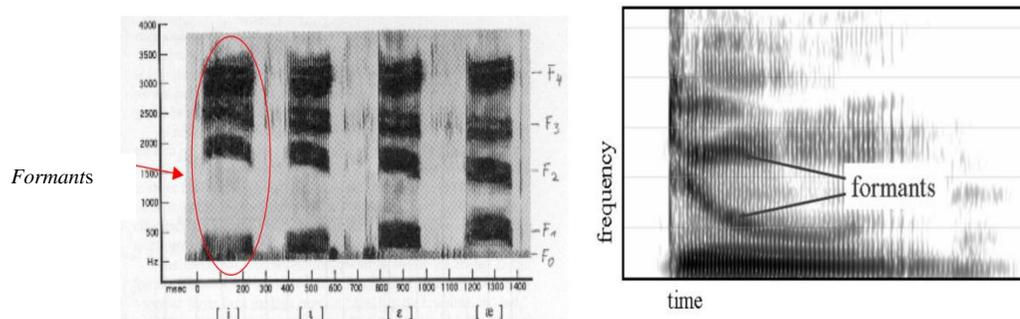

Figure 7: Spectrogram showing Formants

### 2.6. Phonetic Inventory

According to Lan Maddieson<sup>5</sup>, a phonetic inventory could explain all speech sounds, regardless of this, the sounds are produced correctly or not in a specific language or phonetic inventory is a key which explains the different phonemic sounds in a specifically given language where the set of consonants and vowels are called consonantal and vocalic inventories respectively.

<sup>5</sup> Retrieved 12-8-13: <http://www.wals-online-chapter-consonant-inventories>

There is an acoustic hypothesis for checking the phonetic inventory in the connected speech of a given language. According to this hypothesis, there are many acoustic parameters for the detection of consonants and vowels e.g. amplitude, periodicity and spectrum along with some primary features e.g. voicing, continuant, grave, compact, nasalization, palatalization, pharyngealization, clicks, etc. These auditory features are strong and can be detected in a short period of time. The length is less distinctive feature in the consonants and vowels. Further different less common features among consonants are: discontinuity of air stream, voicing, glottalization, aspiration, voice quality and affrication. This is also applicable to all vowel inventories. The modal vowel inventory is /I, e, a, o, u/ which is present almost in all languages.

### **2.6.1. Consonants**

In 2009, Roach defines different types of consonants in following ways; there are many types of consonants and all have in common is that they obstruct the flow of air in vocal or nasal tract completely or partially. Different consonants behave differently: those which make the maximum obstruction are the *plosives* by making a complete stoppage of the air stream in oral cavity. *Nasal* consonants produce with complete closure of the oral cavity but are less obstructive than plosives and air is released through the nose. *Fricatives* make a considerable restriction to the flow of air but not a complete stoppage. *Laterals* stop the air flow only in the center of the oral cavity, not at the sides and cause minor air closure. Other sounds are known as *approximants*; make very slight obstruction to the flow of air because of which they could almost be thought as semi vowels especially in English.

### 2.6.2. Vowels

Vowels are “the sounds in which there is no obstruction to the flow of air as it passes from the larynx to lips”. Vowels are classified on the bases of front, back, high and low manners of articulation and also named respectively (Roach, 2009). According to Skandera and Burleigh (2005) there are three criteria for the description of the vowels i.e. (i) *the closeness/openness* criterion refers to the distance between the tongue and the palate and also the position of the lower jaws. (ii) *Frontness/backness* refers the case that the body of the tongue pushes forward or backward for the articulation of the front or back vowels respectively if front of the tongue raised high than it will produce central vowel. (iii) *The shape of the lips* can be neutral, spread or rounded in the vowel articulation.

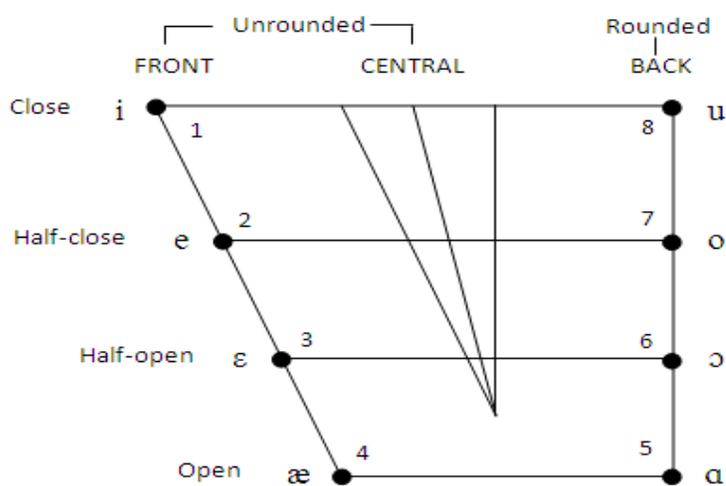

Figure 8: Place & Manner of Articulation in Vowels<sup>6</sup>

### 2.7. Accent Variation

Accent variation could mark the identification of a person as a member of a specific geographical, socio-economic, ethnical group and also identify his first language.

<sup>6</sup> Retrieved 22-9-13: <http://bilingualbambino.blogspot.com/2011/01/variegated-varietals.html>

Phonetically, the accent variation is less or more based on the first three formants; F1, F2 and F3 of the vowels (Accents Research, 2004). The lips rounding and the tongue movement are two basic articulatory positions promptly respond to the first three formants (Ladefoged, 2005).

The variation in formant values occur due to the fact that the vocal tract behaves as a non uniform cross sectional tube. This tube naturally resonates at the multiples of 500 Hz approximately. It produced unequally spaced resonance frequencies therefore it is very difficult to associate formants to a consonant's frequency values. But phoneticians agreed that the quality of the vowel could be quantified by measuring the resonant frequencies of the vocal tract (as cited in Keerio, 2010; Parsons, 1987; Reetz & Jongman, 2008).

The accent variation may cause clear difference in the quality of vowels. Vowels are articulated with the vibration of the vocal folds and relatively open vocal tract therefore produced loud acoustic signals. Formant frequencies are the primary acoustic property of the vowels therefore, first three formants (F1 - F3) are critically important among all formant frequencies. They may vary for the same vowel among the speakers of different sex and age groups; change in the position of articulators in the vocal tract causes the change in the formant frequencies. Therefore, formant frequency location is critically important than the position of the articulators. The exact location of the formant frequencies determines the difference between two vowels. *Frontness/backness* and the *height of the tongue* also define the acoustic properties of the vowels. *Vowel height* is inversely correlates with the first formant frequency (F1) i.e. the higher the tongue position, lower will be the formant frequencies and produced higher vowels.

Frontness/backness is reflected in the second formant; F2. If the *lips are more rounded* and the *tongue body moves backward* than the resultant produced F2 will be lower; conversely the higher the F2 value the lips remain either spread or neutral than the more forward is the tongue body in the mouth. The front vowels are related with the difference between F1, F2 means that large difference indicates the presence of front vowels and less difference indicates the back vowels. Formant frequencies above F3 do not provide much information about the quality of the vowel but the formant frequencies of F4 and F5 seem more speaker specific and may provide information about the speaker's identity (Reetz & Jongman, 2008).

## **2.8. Multilingualism**

Multilingualism is a complex field as is obviously clear from the prefix; multi-, is dedicated to the study of comprehension, processing and production of two or more than two languages. Though, in colloquial usage the term “bilingualism” is used as an umbrella term to embody both bilingualism and multilingualism. In its primary stages of exploration, multilingualism is a “rapid growing linguistic area” which deals with the language contacts, linguistic variations, and language changes (Bhatia & William, 2013).

Multilingualism can be explained in many ways but basically, it suggests the ability of an individual to use more than two languages in a situation. Multilingualism can be explained at two levels i.e. the individual level and the societal level. At *the individual level*, multilingualism refers to the competence of a speaker to use two or more languages. At *the societal level* the term multilingualism refers to the use of two or more than languages in a community but it does not mean that all the speakers are equally competent and proficient in more than one language. There are different factors to

influence multilingualism. Communication, education, religion, cultural identity after migration, socio-economic needs for survival in the society and historical or political movements are most important factors causing multilingualism in all over the world (Gorter et al. 2003).

A man is blessed with inevitable senses where listening and speaking abilities are the favors of Allah Almighty on human beings. Of course, the other senses working normally are also the great blessings. At the time of birth, a child is blessed with the language to learn by listening in an environment and explores the whole universe by using listening and speaking abilities. Language is a mean of communication and has its own uses and abuses in our lives. Language has its own moral and ethical values. It is the soul of all trainings and education either belonging to any domain; moral, political, social, spiritual, relating to arts and humanities, economics, science, technology and so on. Mean while we are unable to refuse the importance of mother language in our lives. The phenomenon of the mother language eventually relates with the multilingualism which causes unity (for the speakers of same mother language) and diversity (for the speakers of other mother languages) at a same time. Different psycholinguistic researchers define multilingualism as the use of two or more than two languages. But multilingualism also deals with the cause and effect of one language to the other and may be problematic sometimes (Mughal, 2011).

A human language is a hierarchical process, learned relatively with dynamic changes, a self governing system of meanings which generates syntagmatic and paradigmatic signs. This language system is used to signify and communicate by means of speech communities within the life cycle. This definition captures the important

ideology of a language as a cultural and neurological phenomenon. A language is an obvious matter which does not develop independently outside the cultural perspective (Andrews, Frigau, Voyvodic, Wright, & Voyvodic-Casabo, 2013).

There are 6912 languages in all over the world but most of them are considered as dialect or a variety of a language (as cited in Gorter et al. 2003; Gordon, 2005, [www.ethnologue.com](http://www.ethnologue.com)). To be a bilingual or multilingual is not an abnormality as supposed by many people but it is a normal and typical need for the majority of population in the world today (as cited in Gorter et al. 2003; Edwards 1994\*: 1). The importance of multilingualism at the psycholinguistic level: “The primary question for linguistics should not be Chomsky’s (1986) “What constitutes knowledge of language” (p.3), but “What constitutes knowledge of languages?” (as cited in Gorter et al. 2003; Cook 1992: 579).

Actually, languages are not individual entities rather are continuum that vary along a geographical areas and sometimes have no clear boundaries among them. Now a days, linguistic variation and diversity are up raising and important social issues for the languages of the world. The language sustainability is also the major issue to flag for preserving the living languages in the world as the people of all living (endangered) languages are facing lingual threats. Language is the “cultural asset” for establishing relationship between linguistic and economic diversity for the welfare of human beings. The different governments of several countries give official and administrative acknowledgment to only one language which creates the impression that multilingualism is not a widespread phenomenon in the world. But in reality, it would not be easy to find

a monolingual country. In all over the world, the majority of the population can speak more than one language at a time (Gorter, et al., 2003).

Multilingualism is not a compromise but is the crucial reality in a society. The presence of different languages in a country or a state is an attributive quality of the globalization effect. The other idea is the migration of the people, the educational changes, the instructive modifications at the work place, the research and the use of new technologies will also support social adjustments and conscious awareness for the acceptability of the linguistic diversity in a society (Rovira, 2007).

### **2.8.1. Multilingualism in Pakistan**

Pakistan is a multilingual country with six majorly spoken and almost seventy two minor spoken languages where fifty are dialects and there is no unique and independent writing system for dialects (Gordon, 2005). In Pakistan, there are 139 districts having different native languages along with Urdu and English as official languages (Mahmood, 2004). Urdu is the mother tongue of only 7.57 percent of the population (Zia, 2011).

As we are firstly and lastly are Pakistanis despite the fact that we are Punjabi, Sindhi, Balochi, Pakhtun and Saraiki by birth therefore, we are supposed to use Urdu as a national language. But the provincial or local languages are our cultural heritage therefore have right to flourish, develop and play their roles. Along with the national language, provincial languages (Punjabi, Sindhi, Baloch, Pashto and Saraiki) could be used in a provincial assembly by the law. On 23<sup>rd</sup> March 1956, Urdu and Bengali were declared National Languages of Pakistan (Article no 6, 1956 Act). But it was decided later in the constitution of 1973, article no. 251;

“Without prejudice to the status of the National language, a Provincial Assembly may by law prescribe measures for the teaching, promotion and use of a provincial language in addition to the National language” (Mahmood, 2004).

Figure 9: Geographical Division of Pakistan<sup>7</sup>

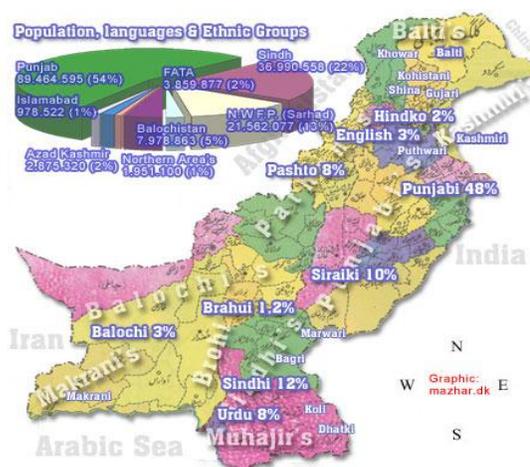

Figure 10: Language Division in Pakistan<sup>8</sup>

### 2.8.1.1. Multilingualism in Punjab

Punjab is the province of Pakistan, having 43,036,404 number of population<sup>9</sup>. In Punjab, there are almost 36 districts (Zia, 2011) and 30 minorly spoken languages are being used such as; Are, Awankari, Chinavari, Chhachi Dhani, Derawali, Dogri, Ghebi, Gujrati, Haryanvi, Hindko, Jangli, Jandali or Rohi, Jhangochi, Jhangvi, Khatki, Khetrani, Majhi, Malwi, Multani, Pahari, Persian, Pothohari, Raangri, Rajisthani, Rachnavi, Riasati, Saraiki. Shah Puri, Saraiki, Thalochi<sup>10</sup>. While Punjabi is the mother tongue of the people living in Punjab but unfortunately the people of Punjab are very redundant to use

Punjabi in their social circle therefore, Urdu and English are the official languages and formal languages (Rehman, 2002).

Figure 11: Geographical Division of Punjab<sup>11</sup>

### 2.8.1.2. Multilingualism in Sindh

According to the census of 1998, in Sindh, the estimated population rate<sup>12</sup> was 14,839,862, there are 23 districts (Zia, 2011) and almost 34 minor languages are being used among people such as; Are, Bhaya, Dhatki, Ghera, Goaria, Gujrati, Gurgula, Hasoria, Hazaragi, Jandawera, Katai Meghwar, Kuchi Bill, Kabutra, Kachichi, Koli Parkari, Koli, Kachi, Lasi, Marwari, Matli, Memoni, Mewasi, Nairya, Od, Rabari, Persian, Rardro, Saraiki Sansi, Sindhi Bhil, Tharadari, Vaghri, Wadiyara, Zalavaria Koli<sup>13</sup>. Sindhi is the mother tongue as well as the official language but Urdu is intelligible only among the educated people who are living in the urban areas (Rehman, 2002).

According to the geological and archaeological researches; Sindh is a sea-born land. In 1920s, the discovery of Moen-Jo-Daro (means mounds of dead) revealed that a

highly developed culture had existed in Sindh (during the era of 2600 and 1900 B.C.) which is as old as Chinese civilization, the ancient Egyptian and Mesopotamian (as cited Keerioayaz, 2010; Advani, 1993; Pithawalla, 1935).

Figure 12: Geographical Division of Sindh<sup>14</sup>

### 2.8.1.3. Multilingualism in Balochistan

Balochistan is the province of Pakistan with 1,568,780 population size<sup>15</sup>. In Balochistan, there are 30 districts where Balochi is the mother tongue of the population. Most of the people understand and speak Urdu as an official language (Zia, 2011). Despite of the limited population, Balochistan has an uncommon tribal and racial diversity therefore can understand and speak more than two languages (Rehman, 2002). But there are almost 12 minor languages being spoken in Balochistan: Arabic, Brahui,

Dehwari, Hazaragi, Jadgali, Khetrani, Lasi, Pashto, Persian, Punjabi, Saraiki, Sindhi, Waneci, Wanetsi (Pashto dialect)<sup>16</sup>.

Figure 13: Geographical Division of Balochistan<sup>17</sup>

#### 2.8.1.4. Multilingualism in Khyber-Pakhtunkhwa

In Khyber-Pakhtunkhwa, the number of districts are 25 (Zia, 2011) and almost 35 minor languages are being used at sub-district level such as; Badeshi, Bashgali, Bateri, Chilisso, Dameli, Dari, Gawar Bait, Gowro, Gujari, Hazaragi, Hindko, Kalkoti, Kalasha, Kalami, Kamviri, Kati, Khovar, Kohistani, Ormuri, Phalora, Persian, Pothohari, Punjabi, Savi, Shina, Saraiki, Turwali, Ushujo, Wakhi, Yidgha but Pashto and Urdu are the majorly spoken languages<sup>18</sup>. As Pashto is the mother tongue and Urdu is an official language of Khyber-Pakhtunkhwa (Rehman, 2002).

<sup>16</sup> Retrieved 12-8-2013: <http://www.omniglot.com/writing/languages.htm>

<sup>18</sup> Retrieved 12-8-2013: <http://www.omniglot.com/writing/languages.htm>

Figure 14: Geographical Division of Khyber-Pakhtunkhwa (NWFP)<sup>19</sup>

### 2.8.1.5. Multilingualism in FATA

In FATA, there are 13 districts (Zia, 2011) and almost 9 minor languages are being spoken by the population (Rehman, 2002) i.e. Dogri, Gojri, Kashmiri, Kundal Shahi, Mirpuri, Majhi, Pahari-Potwari and Potwari are being used along with the Urdu<sup>20</sup>.

Figure 15: Geographical Division of FATA<sup>21</sup>

### 2.8.1.6. Multilingualism in Azad Kashmir

In Kashmir, there are 10 (Zia, 2011) districts and almost 9 minor languages<sup>22</sup> are being used for communication (Rehman, 2002) such as Dogri, Gojri, Kashmiri, Kundal

<sup>19</sup> Retrieved 12-8-2013: <http://www.googlemaps>

<sup>20</sup> Retrieved 12-8-2013: <http://www.omniglot.com/writing/languages.htm>

<sup>21</sup> Retrieved 12-8-2013: <http://www.googlemaps>

Shahi, Majhi, Mirpuri, Pahari Potwari, Punjabi and Urdu are also intelligible by the native people.

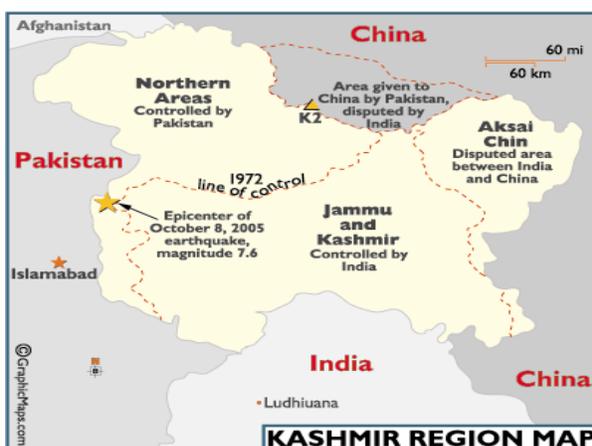

Figure 16: Geographical Division of Azad Kashmir<sup>23</sup>

#### 2.8.1.7. Multilingualism in Gilgit-Baltistan

In Gilgit-Baltistan, there are 7 districts (Zia, 2011) where people use almost 7 languages<sup>24</sup> (Rehman, 2002) such as Balti, Burushaski, Chainies, Domaaki, Gojal, Shina, Wakhi, along with Urdu as an official language.

## 2.9. Six Majorly Spoken Languages in Pakistan

Pakistan is a multilingual country where minor languages are comprehended and used by minority of population therefore are called minor languages and major languages are those understood by majority of population (Gordon, 2005). There are six majorly spoken languages in Pakistan i.e. Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. Brief introduction of these languages are discussed here.

### 2.9.1. Urdu

According to Ethnologue (2005), Urdu is being spoken by 100 million people in all over the world. It is partially spoken and more than partially understood in South Asian countries i.e. Bangladesh, India and UAE. Urdu is a Turkish word which means “*Camp or Army with its followers*” and major languages participating in the camp of Urdu e.g. Arabic, English, Persian and Portuguese (as cited in Saleem et al., 2012; Saksena).

When the Congress started the movement of ‘Hindi Hindustani’ Quaid-e-Azam Muhammad Ali Jinnah said: “We know the real object of this scheme is to throttle Urdu”. Then, in 1938, Quaid-e-Azam replied to Pandit Jawahar Lal Nehru in answering a question: “Another demand of Muslims is concerning the language and transcription. Urdu is our practically national language. We want constitution protection that Urdu shall not be adversely affected or destructed in any manner.” Again in 1941, Hazrat Quaid-e-Azam Muhammad Ali Jinnah said in his address at Aligarh University: “Let me live in Pakistan leading my life in the light of Islamic history and my own culture and according to my own traditions and keeping my Urdu language intact.” Quaid-e-Azam Muhammad Ali Jinnah was always in favor of Urdu as a national language of all the Pakistanis,

without any provincial prejudice. During his struggle for Pakistan, in 1946, when the first prime minister, Sir Feroz Khan Noon wanted to deliver his speech in English, Quaid-e-Azam got involved in and asked him to alter his decision for the selection of Urdu in place of English: “The official language of Pakistan shall be Urdu”. Quaid-e-Azam Muhammad Ali Jinnah declared Urdu as a national and official language at Dacca Airport in 1948: “The national and official language of Pakistan shall be Urdu alone” (as cited in Mughal, 2011).

In Pakistan, Urdu has been declared as a National language under the constitution of Pakistan in 1973. According to the Article 251 (1) “The National language of Pakistan is Urdu, and arrangements shall be made for its being used for official and other purposes within fifteen years from the commencing day”. Urdu and English would be used in writing newspapers, applications, publication of notices and proceedings in courts. The national language, Urdu plays a uniting factor in a democratic society of Pakistan. Being Pakistanis, it is our democratic duty to stick with the *Ideology of Pakistan* by using Urdu in our daily lives. As the purpose behind, “*Nationalizing Urdu*” was to preserve our cultural identity as a nation with our religion, Islam (Mughal, 2011).

### **Phonetic Inventory**

Urdu is phonetically similar to Hindi but is different in alphabetical script and historical characteristics. The pronunciation of Urdu varies with reference to the geographical changes in Pakistan. It is a rich language with a large variety of sounds and all of these sounds can be differentiated on the basis of duration, quality and nasalization (Rehman, 2006).

There is a controversy in the total number of consonants in Urdu language. As according to Hussain (1997) and Raza A. A.(2009) there are thirty six consonants but according to some other studies, there are forty three (Qandeel, Mahmood, & Mahmood, 2012) or forty four consonants (Raza A. A., 2009). The confusion in the number of consonants in Urdu is due to the traced consonants such as; aspirated nasals /m<sup>h</sup>/ and /n<sup>h</sup>/ aspirated lateral /l<sup>h</sup>/, aspirated flap /ɽ<sup>h</sup>/ and aspirated trill /r<sup>h</sup>/ (Oxford Urdu English Dictionary, 2013; as cited in Qandeel et al., 2012; Raza A. A., 2009; Saleem et al., 2002). Urdu has Uvular stop sound /q/. It also has borrowed sounds /x/, /ɣ/, /f/ and /z/ which are substituted with /k<sup>h</sup> /, /g/, /p<sup>h</sup> / and /dʒ/ respectively but these sounds are being observed only in the speech of educated people in Pakistan (as cited in Qandeel, 2012; Shackle, 2003).

(As cited in Oxford Urdu English Dictionary, 2013; Saleem et al., 2002)

Table 1: Urdu Consonantal Inventory

	Bilabial	Labio-dental	Dental	Alveolar	Retro flex	Palatal	Velar	Uvular	Glottal
<b>Stop</b>	p b p <sup>h</sup> b <sup>h</sup>		ʈ ɖ ʈ <sup>h</sup> ɖ <sup>h</sup>	t d t <sup>h</sup> d <sup>h</sup>			k g k <sup>h</sup> g <sup>h</sup>	q	ʔ
<b>Fricative</b>		f v		s z		ʃ ʒ	ɣ	x	h
<b>Affricates</b>				tʃ dʒ tʃ <sup>h</sup> dʒ <sup>h</sup>					
<b>Nasal</b>	m m <sup>h</sup>		n n <sup>h</sup>				ŋ		
<b>Lateral</b>				l l <sup>h</sup>					
<b>Trill</b>						r r <sup>h</sup>			
<b>Flap</b>					ɽ ɽ <sup>h</sup>				
<b>Glide</b>		(w)				j			

## **Vowels**

There are 7 long and 3 short oral and nasal vowels, 3 medial oral vowels (Oxford Urdu English Dictionary, 2013) and a number of diphthongs have also been reported in Urdu language by the Center for Language Engineering, UET, Lahore ([www.cle.org.edu.pk](http://www.cle.org.edu.pk)).

### **Short Vowels**

There are 3 short vowels in Urdu language i.e. /ɪ/, /ə/ and /ʊ/ (Oxford Urdu English Dictionary, 2013; as cited in Qandeel et al., 2012; Raza A. A., 2009; Saleem et al., 2002).

### **Medial (Majhul) Vowels**

According to Oxford Urdu English Dictionary (2013) Urdu language also has 3 medial vowels i.e. /e/, /æ/ and /o/. They show mixed properties of short and long vowels means that the medial vowels are audible like long vowels but their duration is larger than short vowels and lesser than long vowels. Most of the time medial vowels are followed by /h/ sound. There is no separate symbol IDs for medial vowels in IPA. Therefore, same symbols are used for long and medial vowels. But for making the difference between long and medial vowels the duration mark (:) is used with long vowels.

## Long Vowel

In Urdu, there are 7 long oral vowels i.e. /i:/, /e:/, /æ:/, /a:/, /ɔ:/, /o:/ and /u:/ (Oxford Urdu English Dictionary, 2013; Qandeel et al., 2012; Saleem et al., 2002).

## Nasal Vowels

Urdu language has contrastive nasal vowels, equal in number to oral vowels i.e. /ĩ:/, /ẽ:/, /ã:/, /ã̃:/, /õ:/, /õ̃:/ and /ũ:/ (Zahid, 2010).

(Quardileteral of Urdu oral and nasal vowels by Raza A. A., 2009)

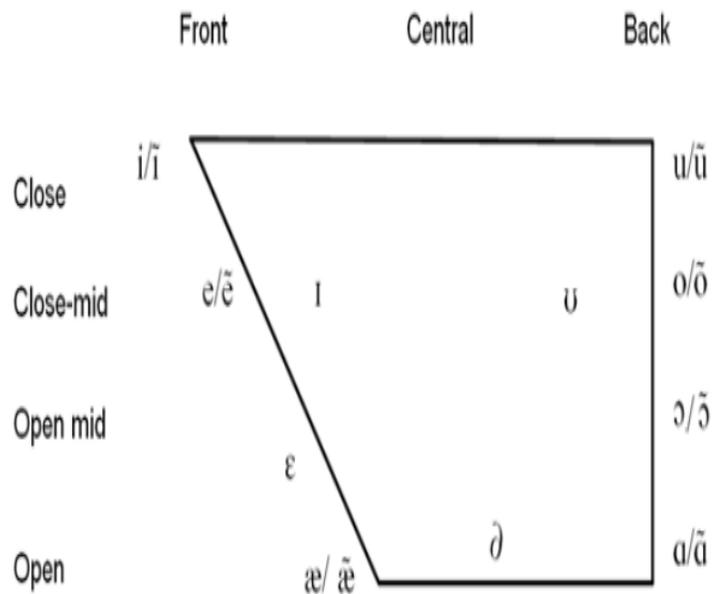

Figure 18: Contrastive Urdu Vowels

List of oral and nasal vowel is given below used in prototype speech annotation at Center for Language Engineering, 2014 ([www.cle.org.edu.pk](http://www.cle.org.edu.pk)).

Table 2: *Oral & Nasal Vowels in Urdu*

Sr. no.	Oral Vowel	IPA	Nasal Vowel	IPA

8	CVVC

## Lexical Stress in Urdu Language

Lexical stress is another important feature of Urdu language. It is an abstract phonological phenomenon, assigned to one or more than one syllable in a word of any language depending on different mechanisms. Two hypotheses are more commonly being used to explain lexical stress in any language i.e. *Hyperarticulation theory*<sup>26</sup> and the *Sonority Expansion Theory*. Acoustic phonological cues for the stressed syllable are F0, quality of vowel and duration of the stressed syllable (consonant and vowel) in a word. In Urdu language, lexical stress is marked on the final heavy syllable but on the other hand

---

<sup>26</sup> According to Hussain (1997) Hyperarticulation Theory suggests that all phonemically distinctive contrasts are more distinctively articulated and The Sonority Expansion Theory suggests that stress works to increase the sonority feature. Both theories explain some but not all stress related effects for different languages.

it is assuming that final mora<sup>27</sup> in Urdu is extrametrical and therefore not responsible for contributing the weight to the final syllable. A syllable is considered heavy if it has at least two morae. A short vowel and a coda consonant are mono moraic and a long vowel is bi-moraic which contributes a heavy syllable (Hussain S. , 1997).

### Summary of Urdu Language

- Urdu is a majorly spoken and national language of Pakistan but accent varies geographically (Saleem, Kabir, Riaz, Rafique, Khalid, & Shahid, 2012).
- It is syllable stress language and it has eight syllable templates (Hussain, 2006).
- It is phonetically similar to Hindi but has different alphabets (Saleem et al., 2012).
- There are 66 phonemes in the phonetic inventory of Urdu:
  - Forty three consonants
  - Seven long oral vowels
  - Three medial oral (Majhul) vowels
  - Three short oral vowels
  - Seven long nasal vowels
  - Three short nasal vowels

8	VVC	3

### 2.9.2. Punjabi

Punjabi is an ‘Indo-Aryan language’ and has a rich cultural heritage. In 11<sup>th</sup> century, it is recognized as an independent language and is the 10<sup>th</sup> largely spoken language of the world. It has around 109 million speakers in Pakistan and India who speak Punjabi as their first language which means almost 76 million speakers in Pakistan and 33 million speakers are living in India. In Pakistan, there is no official status of Punjabi language. But in India, it is the first official language in Punjab and in the other provinces is one of an official language along with other 22 languages (Ghai & Singh, 2013).

Punjabi has a large number of speakers but is called a Less Resource Language (LRL) on the account of non availability of the electronic resources. It is also called an inter-continental language (Lata, 2011).

Pakistani spoken Punjabi is more influenced with Perso-Arabic sources and it has different dialects such as Multani, Lehandi and Pothohari, etc. These dialects are different from each other at both phonemic and word level. In India, it is influenced by Sanskrit and is also considered a sister language of Hindi. In Punjabi, *tone* is segmental and phonemic in function which causes pitch variations for distinguishing the different meanings of a word that has same vowel and consonant pattern (Karamat, 2012). During the production of a tone, there is neither air friction nor air stoppage occurs in the oral tract which makes Punjabi language phonologically complex, contrastive (Lata, 2011) and unique among other Indo-Aryan languages (Qandeel et al., 2012).

*Nasalization* is another important but less understood feature by the Punjabi speakers. The oral sounds are produced with the configuration of oral and nasal tract; the

complete closure of nasal tract produces nasal vowels with the open velopharyngeal port. There are two types of nasalization i.e. *contrastive* nasalization and *contextual* nasalization. The nasalization due to the effect of neighboring nasal sounds is called contextual nasalization and the nasalization produced with the alternation of minimal pairs of oral and nasal vowels is called contrastive nasalization. So, by the change of a nasal vowel with the oral vowel the meaning of the word would be changed (Zahid, 2010).

**Stress** is not a major feature in Punjabi but helps in distinguishing the disyllabic grammatical words. In Punjabi, all stressed syllables are accented and the accent is the combination of pitch and length therefore, unstressed syllables have lack of pitch and length. **Intonation** is the fluctuation in the pattern of pitch as applied to a larger unit than the word. A clause or a sentence could be uttered in more than one way by giving different meaning to the hearer (Lata, 2011).

### **Phonetic Inventory**

In Pakistan, Punjabi has been written in Arabic script and is called Shahmukhi but in India is written in Devangari script and is called Gurumukhi. Punjabi consonants have been divided into six groups (Ghai & Singh, 2013). It is very difficult to find out the exact consonantal inventory of Punjabi language because each author presents a slightly different phonetic inventory by the other. Shahmukhi Punjabi has 31 consonants (Qandeel et al., 2012) and Gurumukhi Punjabi has 35 consonants, 10 vowels, 7 diphthongs and 3 tones (Lata, 2011). The Punjabi stop system of consonants is similar to

Urdu and Hindi but the historical voiced aspirates are replaced with three tones (Bakst, 2012).

There is controversy in the declaration of places and manners of phonemes in Punjabi inventory. According to Lata (2011) and Karamat (2010) the phonemes; /f/ and /v/ are labiodental fricatives but only Qandeel et al. (2012) reported /f/ and /v/ as bilabial fricatives and on the other hand, Lata (2011) has also reported bilabial approximant /w/. There is also a confusion about the phonemes; /ʃ/, /ʃʰ/ and /dʒ/ as palatal stops (Qandeel et al., 2012; Karamat, 2010) or as palatal affricates Lata (2011).

Punjabi also has different borrowed phones (/x/, /ɣ/, /f/ and /z/) from Persian and Arabic (Qandeel et al., 2012; Karamat, 2010). It also has a set of voiceless aspirated stops; /pʰ/, /tʰ/, /tʰʰ/ and /kʰ/ (as cited in Qandeel et al., 2012; Mahmood, 2011).

Table 4: *Punjabi Consonantal Inventory by Lata, 2011*

	Bilabial	Labio-dental	Dental	Alveolar	Retroflex	Palatal	Velar	Glottal
<b>Stops</b>	p p <sup>h</sup> b		t t <sup>h</sup> d		t t <sup>h</sup> d		k k <sup>h</sup> g	
<b>Fricatives</b>		f v		s z		ʃ	x y	h
<b>Affricates</b>						ʃʃʰ dʒ		
<b>Nasals</b>	m			n	ɳ		(ŋ) <sup>28</sup>	
<b>Laterals</b>				l	ɭ			
<b>Flaps</b>				r	ɽ			
<b>Approximant</b>	(w)					j		

<sup>28</sup> Velar nasal /ŋ/ has reported only by Karamat (2010)

## Vowels

In Punjabi language, there are 10 vowels and exist in pairs i.e. a long vowel and a short vowel (Ghai & Singh, 2013). Different sources claim different number of Punjabi vowels e.g. the variation in the number of short vowels is; short vowel /ɪ/ and /ʊ/ change with stress into short form of /e/ and /o/ respectively. This important variation of vowels is clearly visible in the following diagram by showing the place of articulation of vowels by Karamat (2010).

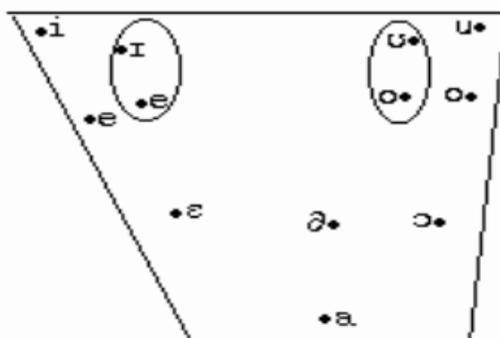

Figure 19: Punjabi Vowels

Table 5: Punjabi Oral Vowels

	Ghai & Singh (2013)		Karamat (2010)	
	Short Vowels	Long Vowels	Short Vowels	Long Vowels
1	ə	a:	ə	a:
2	ɪ	i:	ɪ	i
3				e
4	e	ɛ:		ɛ
5	ʊ	u:	ʊ	u
6				o
7	o	ɔ:		ɔ

## Nasal Vowels

Punjabi language has nasal vowels in contrast of all oral vowels. So, there is larger possibility of *contextual* and *contrastive* nasalization in connected speech. The Punjabi speakers showed relatively greater degree of nasalization for /ã/, /ã̃/, /ã̃:/, /ã̃/, /ĩ/, /ĩ:/ but less for the short vowel /ʌ/ and also nasalize both low and high vowels but showed greater nasality for low vowels (Zahid, 2010).

Table 6: *Contrastive Nasal Vowels in Punjabi*

Sr. no.	Short Nasal vowel	Long Nasal Vowel
1	ã	ã:
2	ĩ	ĩ:
3	ã̃	ã̃:
4	ẽ	ẽ:
5	õ	õ:
6	õ̃	õ̃:

## Semi Vowels

There are two semi vowels or approximants in Punjabi i.e. /w/ and /j/ (Ghai & Singh, 2013).

## Syllable Templates in Punjabi

According to Ghai and Singh (2013), there are 7 templates of Punjabi syllables i.e.

Table 7: *Punjabi Syllable Templates*

## Summary of Punjabi Language

- According to Karamat (2002), Punjabi is culturally rich Indo-Aryan language since 11<sup>th</sup> century.
  - Lehandi, Multani, and Pothohari are three spoken dialects of Punjabi in Pakistan.
  - It is a tonal language and its three different tones make it phonemically difficult language.
- It is largely spoken language in Pakistan and India; still called less resource language due to the unavailability of the electronic resources (Lata, 2011).
- It has no official status in Pakistan (Ghai & Singh, 2013).

- Nasalization also makes it difficult language (Zahid, 2010).
- There are fifty eight phonemes in Pakistani Punjabi:
  - Thirty one consonants
  - Ten oral vowels
  - Twelve nasal vowels
  - Seven diphthongs

### 2.9.3. Sindhi

Sindhi is also a majorly spoken language in Pakistan<sup>29</sup>. In 1996, it is ranked as the 50<sup>th</sup> largely spoken language of the world<sup>30</sup>. The rate of population for this ranking is outdated now. According to the census of 1981, there were 19 million Sindhi speakers in Pakistan whereas according to the census of 1998, the figure of the population in Sindh was 30.4 million speakers<sup>31</sup>.

In Sindh, Sindhi is first language and both Urdu and English are used as second languages in schools and offices. In 2005 Jennifer said, Sindhi language is facing different socio-economic and socio-lingual dangers by Urdu and English languages in Pakistan. Grimes (2001) and David (2003) believed, the other factors such as poor literacy rate (45.29% in 1998 census), social prestige, mass migration, lack of research and developmental resources are becoming the cause of hesitation among the native speakers, shifting to the other prestigious and more prominent languages<sup>32</sup>. All these factors are the cause of reduction in the population of native Sindhi speakers. Others factors are potential threats including the reduction of speakers, less prestige, increase in

<sup>30</sup> Retrieved 14-11-2013 <http://www.davidpbrown.co.uk/help/top-100-languages-by-population.html>, <http://www.photius.com/rankings/languages2.html>

<sup>31</sup> Retrieved 14-11-2013: <http://www.ststpak.gov.pk/>

<sup>32</sup> Retrieved 14-11-2013: <http://www.sindh.gov.pk/aboutsindh.htm>

the rate of urbanization where parents are hesitant to impart Sindhi as mother tongue to their children. The other most important factor is that Sindhi language is difficult to learn because of the large number of phonetic elements (Keerio, 2010).

There is very limited work done in Sindhi linguistics due to migration after the partition of the sub-continent. Before partition, Grierson's work (1919) titled as *Linguistic survey of India*, Ernest Trumpp's work *Grammar of the Sindhi Language* and the work of Sir John H. Marshall titled; *Mohenjo-Daro and the Indus Civilization*, provides a solid historical and linguistic background of Sindhi language along with the geographical discussion but lacks the information of acoustic phonetics (as cited in Keerio, 2010).

The notable work in the acoustic analysis of the voiced implosives<sup>33</sup> of Sindhi has been done by Raza et al. (2004). The study on the segmentation of Sindhi language was carried out by Khawaja et al. (2007) on tracking the dynamics of formants but he has lacking the information about how the segmentation was achieved for the phoneme classes such as the vowels, diphthongs, liquids and glides etc. Other areas in Sindhi language are articulatory phonetics, grammar, orthography and morphological structure refer to the work of authors in this respect (as cited in Keerio, 2010: Trumpp, 1872; Grierson, 1919; Advani, 1993; Jatoi, 1996; Jennifer, 2006).

The research in the field of acoustic phonetics of Sindhi language was ignored a lot. But the work of Keerio (2010) deals with the acoustic phonetic characteristics of the language elemental sounds, accent specific acoustic variations, compilation of

---

<sup>33</sup> An implosive consonant is produced with the lowering glottis (as down word movement of the piston by creating a short rarification of the air in mouth. When the stricture in mouth released the air moves into mouth (Webster's New World College Dictionary, 2010)

meaningful phonemes with great emphasis on the unique phonetic and linguistic characteristics and easy to learn sound system of Sindhi language.

### **Phonemic Inventories**

Sindhi language uses two writing scripts; Urdu and Hindi which is considered one language with two scripts<sup>34</sup>. While the modern Sindhi uses the *Arabic Nask Script* (among Muslim Sindhi speaker areas) and *Devanagri* script (among Hindu Sindhi speaker areas). But the speaking style of Muslims and Hindus is similar to each other (as cited Keerio, 2010; Jennifer, 2006; Khawaja, 2004).

There are six dialects in spoken Sindhi language in Sindh, Pakistan and name of them are; Thareli, Lasi, Lari, Vicholi (Middle dialect), Utradi and Kachhi. Vicholi or Middle dialect is taken as a standard and is also discussed with reference to linguistic similarities and diversities in detail. Vicholi is important because it shares geographical boundaries with all the other Sindhi dialects. Sanghar district is associated with Vicholi dialect although the dialect of this region is slightly different from middle dialect, Vicholi (Keerio, 2010).

In Sindhi language, there are six consonant classes; stops, implosives, nasals, fricatives, liquids and flaps. Monophothongs, diphthongs and glide consonants are also present. It has forty one consonants and ten vowels. Its phonemic inventory is consisted of the large number of stop consonants ; /p/, /b/, /p<sup>h</sup> /, /b<sup>h</sup> /, /dʒ/, /dʒ<sup>h</sup> /, /tʃ/, /tʃ<sup>h</sup>/. There are very limited languages in the world which have implosive stops; among them Sindhi, Swahili and Hausa are included. It has contrastive implosive stops; /ɓ/, /ɗ/, /ɟ/, /ɗ̥/. Sindhi implosives are produced with vibrating vocal cords; therefore are referred as voiced

---

<sup>34</sup> Retrieved 21-11-13: <http://www.indianchild.com/hindi.htm>

consonants (Keerio, 2010). These are completely non-aspirated glottal ingressive sounds which are produced by lowering the larynx with vibrating vocal cords (as cited in Keerio, 2010: Jennifer, 2006; Raza, 2004; Nihalani, 1986). In Sindhi language, there are four affricate consonants; /tʃ/, /tʃ<sup>h</sup>/, /dʒ/, /dʒ<sup>h</sup>/ (as cited Keerio, 2010: Jennifer 2006; Raza, 2004). But there is controversy regarding these consonants in Sindhi language because few authors have classified affricates as stops in Sindhi language (as cited in Keerio, 2010: Mirza 2006; Ladefoged, 1996; Jatoi, 1996).

(Consonantal phonetic inventory of Sindhi language by Keerio, 2010)

Table 8: *Sindhi Consonantal Inventory*

	<b>Bilabial</b>	<b>Dental</b>	<b>Alveolar</b>	<b>Retro- flex</b>	<b>Post- alveolar</b>	<b>Palatal</b>	<b>Velar</b>	<b>Uvular</b>	<b>Glottal</b>
<b>Plosives</b>	p    b p <sup>h</sup> b <sup>h</sup> ɓ	t    d t <sup>h</sup> d <sup>h</sup>					k    g k <sup>h</sup> g <sup>h</sup> g̑		
<b>Fricative</b>		f    v	s    z		tʃ    dʒ tʃ <sup>h</sup> dʒ <sup>h</sup> ʃ				h    h
<b>Affricate</b>				t    ɖ t <sup>h</sup> ɖ <sup>h</sup> ɖ̣	ʃ	j		x    ɣ	
<b>Nasals</b>	m		n	ɳ		ɲ	ŋ		
<b>Lateral</b>				l					
<b>Trill</b>				r					

According to Keerio (2010), in Sindhi language, there are five nasal phonemes, bilabial /m/, alveolar /n/, velar /ŋ/, retroflex /ŋ̠/, palatal /ɲ/. It also has two liquid sounds; lateral /l/ and trill /r/. Sindhi trill and lateral class of consonants are jointly referred as liquids. Sindhi liquids have special features i.e. pronounced voiced at the beginning and middle of the words while voiceless at the final position of the words. There are nine fricative sounds; two labiodental; voiced /v/ and unvoiced /f/, glottal voiced /h+/ and unvoiced /h-/ , voiced velar /ɣ/ and voiceless /x/, voiced alveolar /z/ and unvoiced /s/, palatal voiced /j/ and palato-alveolar voiceless /ʃ/.

There are nine redundant alphabet symbols in Sindhi phonemic inventory. Most of these phonemes are borrowed from Persian and Arabic languages are; /s/ ذ ز /z/ س ص ث /s/ ظ /h/ ح /t/ ط /k/ ق /ʔ/ ع. There are three pairs of consonants which create confusion in general conversation for the listeners in identifying the pronounced sound. The sounds of confused consonants are /b/ ب, as /b<sup>h</sup>/ پ the sound /d̪/, ڍ as /d̪̣/, ڍ and the sound /g/, گ as /g<sup>h</sup>/ گھ and vice versa. There are twelve sounds which are not yet part of language alphabets in Sindhi language. They are: (i) /ʔ/, ء (ii) /r/, ر (iii) /d̪r/, ڍر (iv) /la/, لا (v) /t<sup>h</sup>/ ٺھ (vi) /r<sup>h</sup>/, رھ (vii) /l<sup>h</sup>/, لھ (viii) /n<sup>h</sup>/, ڻھ (ix) /m<sup>h</sup>/, مھ (x) /ŋ<sup>h</sup>/, ڻھ (xi) /m̪/, مڻ (xii) /ya/ ی.

In Sindhi language, there are three pairs of interchanging consonants which are used by the speakers of different dialects in communication. For example the speakers of the middle dialect pronounce the word fish as: /məʃ<sup>h</sup>i/, مڇي with /ʃ<sup>h</sup>/, چ sound and the speakers of the Utradi dialect change this sound with sound /ʃ/, ش and pronounce the word fish as: /məʃi/, and in similar way, and the sound /d̪z/, is changed with /z/, ز and the sound /r/, ر is changed with /r̪/, ڙ and vice versa. There are three pairs of substituting

consonants: (i) the sound /x/ خ is substituted with /k<sup>h</sup>/ ك (ii) the sound /f/ ف is substituted with /p<sup>h</sup>/ ف (iii) the sound /g/ گ is substituted with /ɣ/ غ .

### Vowels

According to Keerio, (2010) there are ten vowels in Sindhi language. He has identified the vowels by their minimal pair words means if two words are different by having the difference of only one vowel. But both vowels are produced at identical position then both of these words will have different meanings.

Table 9: *Sindhi Vowels*

	IPA Symbol	Sindhi
<b>1</b>	I ɪ	اي اِ
<b>2</b>	e ɛ	اي اِي
<b>3</b>	ə ɑ	اَ اِ
<b>4</b>	ɔ o	او او
<b>5</b>	ʊ u	اُ او

### Syllable Templates in Sindhi

There are 8 syllable templates in Sindhi language (Keerio, 2010).

### **Summary of Sindhi Language**

- According to Keerio (2010), Sindhi language is 6<sup>th</sup> majorly spoken language in Pakistan.
- It has two written scripts and six dialects; Kachhi, Lasi, Lari, Thareli, Vicholi and Utradi
- Vicholi is the standard dialect of Sindhi.
- It has eight syllable template
- It has fifty two phonemes excluding diphthongs;
  - Forty two consonants
  - Ten vowels

### 2.9.4. Balochi

Balochi is a North West Iranian language and is spoken by almost seven million people (Sabir, 2004). Mostly Balochi speakers belong to Pakistan, Iran, Afghanistan, India, the Arab Gulf States, Turkmenistan, East Africa and also by a number of speakers in North America, Europe and Australia. Balochi language is spoken in South Western Pakistan; Balochistan and small number of population in Punjab and Sindh especially in Karachi. Among other West Iranian languages, Balochi is a controversial language (Ahangar, Oostendrop, & Soohani, 2013). Because it is considered closer to Parthian rather than middle Persian (as cited in Ahangar et al., 2013; Elfenbein 1989). In 2003, Paul declared similarity among Balochi and South Iranian languages and Korn also reported the relationship among Balochi and Iranian languages in the form of a family tree (as cited in Ahangar et al., 2013).

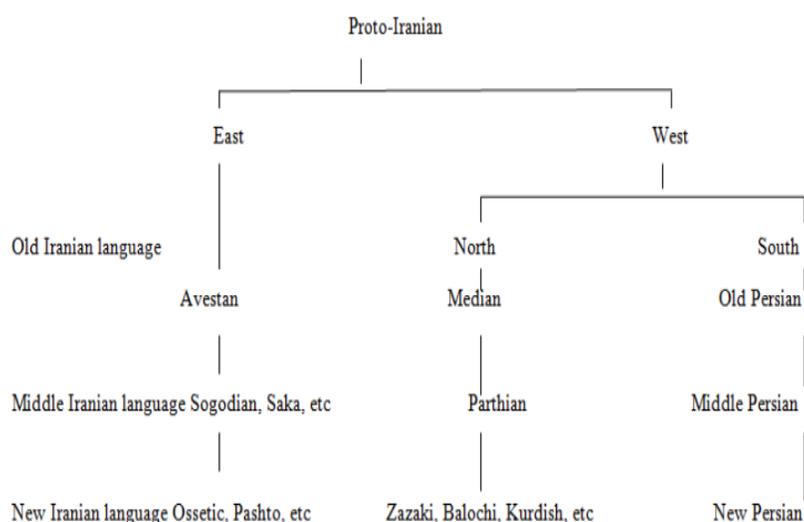

Figure 20: Family Tree of Iranian Languages

According to Sabir (2011), around the world, almost six million people use the *Western* dialect as the standard form of Balochi language. The Central Swarani Balochi (CSB) is a western dialect and has been taken as the standard form of language. It was

also a notion that Balochi was more widely spoken in 19<sup>th</sup> and 20<sup>th</sup> century especially in Punjab and Sindh. But nowadays people who recognize themselves as Balochi are going to switch into other languages like Punjabi, Sindhi, Saraiki etc.

In the number of countries, Balochi is used as a medium of speech but not adopted as an official language. In Pakistan, Balochi language was used only as a spoken language till post colonial period but was used as the medium of instruction at the primary level in Balochistan by 1989 to 1992 during the reign of Nawab Akbar Khan Bugti.

### **Phonetic Inventory**

Balochi language has three main dialects; Western Balochi (WBal.), Southern Balochi (SBal.) and Eastern Balochi (EBal.) which is very broad dialects' division because of this reason, most of the dialects are not easily fit into these groups (Ahangar et al., 2013).

Balochi alphabets were developed during 19<sup>th</sup> century with Roman alphabets devised by Major E. Mockler in 1877. After the independence of Pakistan in 1947, Baloch scholars adopted Perso-Arabic script in writing. Its phonetic inventory is consisted of 25 consonants, 8 vowels and two diphthongs /ai/ and /au/ and the retroflex property of Balochi language is influenced by Indo-Aryan languages (Sabir, 2011).

The uneducated Balochi speakers replaced /f/, /ġ/, /q/ and /x/ with /p/, /g/, /k/ and /h/ respectively and /f/, /ġ/, /q/ and /x/ are found in Arabic and Persian loan words. But the educated population only used Persian pronunciation. Fricative /ɣ/ has been observed in educated people's speech of loan words (Ahangar et al., 2013).

The consonantal inventory of Balochi language (as cited in Ahangar et al., 2013; Baranzehi, 2003) is given below.

Table 11: *Balochi Consonantal Inventory*

	<b>Labial</b>	<b>Dental</b> <b>Alveolar</b>	<b>Retroflex</b>	<b>Prepalatal</b> <b>Palatal</b>	<b>Velar</b>	<b>Glottal</b>
<b>Plosive</b>	p      b	t      d	ʈ      ɖ		k      g	
<b>Affricate</b>				č      ǰ		
<b>Fricative</b>	(f)	s      z		š      ž	(x)    (g)	h
<b>Nasal</b>	m	n				
<b>Lateral</b>		l				
<b>Flap</b>		r	ɽ			
<b>Glide</b>	w			y		

## Vowels

There are 5 long vowels /ā/, /ī/, /ū/, /ē/, /ō/ and 3 short vowels /a/, /e/, /o/ (as cited in Ahangar et al., 2013; Baranzehi, 2003). According to Soohani, in 2003, the number of short vowels is more than the long vowels. There are 4 long vowels /ɑ:/, /i:/, /o:/, /u:/ and five short vowels /ɑ/, /e/, /o/, /æ/, /ə/ (as cited in Ahangar et al., 2013).

Table 12: *Balochi Vowels*

Sr. No.	According to Soohani (2003)		Sr. no.	According to Baranzehi (2003)	
	Long Vowels	Short Vowels		Long Vowels	Short Vowels
1	a:	ɑ	1	a	ɑ
2	i:	e	2	i	e
3	o:	o	3	u	o
4	u:	æ	4	e	
5		ə	5	o	

In 2010, Soohani reintroduces the vowel inventory which is similar to the previous work (2003) except few modifications i.e. she does not consider /ə/ as a vowel and considered long /i:/ as a short vowel (as cited in Ahangar et al., 2013).

### Syllable Templates in Balochi language

There are 6 syllable templates in Balochi Language (as cited in Ahangar et al., 2013; Soohani 2003, 2010).

Table 13: *Balochi Syllable Templates*

Sr. No.	Syllable Templates in Balochi
1	CV
2	CVC
3	CVCC
4	CCV
5	CCVC
6	CCVCC

## Summary of Balochi Language

- According to Sabir (2010) Balochi language has three main dialects; Western Balochi, Southern and Eastern Balochi and Soohani (2003, 2010) also informed about six syllable templates (as cited in Ahangar et al., 2013).
- According to Sabir (2011), Balochi is a North West Iranian language and has seven million speakers all over the world.
  - The native Balochi speakers are diverging to other languages because of socio economic issues.
  - It has no official status in Pakistan but was the medium of instruction during the reign of Nawab Akbar Khan Bugti in Balochistan.
  - There are thirty five phonemes in Balochi language;
    - Twenty five consonants
    - Nine vowels
    - Two diphthongs

### 2.9.5. Pashto

Pashto is an East Indo-Iranian language and there are twenty million Pashto speakers in Pakistan and Afghanistan (Robert, 2000). In 1979, according to a conservative estimation, the total number of speakers in Pakistan is 12 million (including refugees) and 8 million speakers in Afghanistan (Elfenbein, 1997). According to some other researchers, there are forty to fifty thousand people speak Pashto in Pakistan, Iran and Afghanistan. In Pakistan, Pashto is a provincial language in Khyber-Pakhtunkhwa and is also taught till secondary level. In some areas of Balochistan, it is also used as a

spoken language. But it is a native and official language in Afghanistan besides Dari Persian (Din & Rahman, 2011).

### **Phonetic Inventory**

Pashto shares unique property among Iranian languages for having a number of retroflex consonants just like Urdu and Punjabi. This is also true that Urdu and Punjabi are neighboring languages but distantly related with Pashto (Robert, 2000).

According to Din and Rehman (2011), the different dialects and various authors of Pashto language have introduced different number of phonemes. There are five main dialects in Pashto; Yusuzia (North-Eastern dialect), Kandahari dialect (South-Western dialect), Middle Tribal dialect, Central dialect (North-Western dialect), dialect of Quetta (South-Eastern dialect).

According to Elfenbein (1997), it is difficult to describe Pashto phonology. As, Pashto dialects are complexly ramified therefore one has not enough right data to differentiate one dialect from the other dialect. There are various ways in which its dialects can be classified but none of them is entirely satisfactory because of dialectal isoglosses and geographical variations. Therefore, dialects are divided into four classes on the basis of phonology (especially based on the pronunciation of four Pashto consonants i.e. x̣, g̣, c, and j).

Those four dialects are differentiated as;

Northwest Group	Southwest Group	Southeast group	Northeast Group
<b>Semi-hard Group)</b>	<b>Soft Group</b>		<b>Hard Group</b>
x̣ is pronounced ʃ	x̣ is pronounced ṣ	x̣ is pronounced ʃ	x̣ is pronounced x/k <sup>h</sup>
g̣ is pronounced ɣ̣/ẓ	g̣ is pronounced ẓ	g̣ is pronounced ʒ	g̣ is pronounced /g/
/c/ is pronounced /s/	/c/ is pronounced /tʃ/	/c/ is pronounced /tʃ/	/c/ is pronounced /s/
/j/ is pronounced /z/	/j/ is pronounced /dʒ/	/j/ is pronounced /dʒ/	/j/ is pronounced /z/

In Pashto language, there is a controversy in the number of consonants; 26 (Din & Rehman, 2011) or 30 (Robert, 2000) and the cause of difference between phonetic inventories; may be the ‘nativeness effect of the language. Yusafzai dialect of Pashto language is taken as a standard dialect. There is controversy in the presence of fricatives in Pashto language. All the phonemic information of Pashto language shows that labiodental fricatives e.g. /f/, /v/, /θ/, /ʒ/ and /ð/ are not existing (Din & Rehman, 2011) but Robert (2000) reported the labial fricative /f/.

According to Din and Rehman (2011), in Pashto /w/ is glide without lip roundedness. Labiodental voiced fricative has been observed as a noisy bilabial /w/. The dental voiceless fricative has been observed as dental voiceless stop. There is no labial and dental fricatives but these sounds are pronounced similar to the dental stops found in Southern Irish English. The dental voiced fricative has been pronounced as dental voiceless stop by some of the native speakers because of the orthography of the sounds written with ‘th’ which are pronounced as dental voiceless stop. The post alveolar voiced

fricative is pronounced like a post alveolar voiced affricate of English. /ʒ/ is pronounced as velar voiced stop because of the presence of /dʒ/ in phonemic inventory.

Pashto language has retroflex nasal sound /ŋ/ but has no labial and labiodental fricatives (Ijaz, 2002-2003). The major difference between Southern dialect (spoken in Balochistan, Waziristan and Banu areas) and Yusufzai dialect (spoken in Peshawar) is; /ɸ/ and /dʒ/ are consistently present in Southern dialect while in Yusufzai dialect are pronounced as /s/ and /z/ (Elfenbein, 1997).

Table 14: *Pashto Consonantal Inventory (Elfenbein, 1997)*

	<b>Bilabial</b>	<b>Dental</b>	<b>Palato- Alveolar</b>	<b>Retroflex<sup>35</sup></b>	<b>Velar</b>	<b>Uvular</b>	<b>Glottal</b>
<b>Plosives</b>	p b	t̪ d̪		ṭ ḍ	k g	(q)	(ʔ) <sup>36</sup>
<b>Fricative</b>	(f) <sup>37</sup>				x ɣ <sup>38</sup>		h
<b>Affricate</b>		c j	c̣̥ j̣̥				
<b>Spirants</b>		s z	ṣ̥ ẓ̥	x̣̥ g̣̥			
<b>Nasals</b>	m	n		ŋ̣̥	ŋ		
<b>Lateral</b>		l					
<b>Flap</b>		r		ɽ			
<b>Glides</b>	w		y				

Stress is the most important element in Pashto language. But the phonetic characteristics, coalescence and controversial patterns of vowel harmony affect the stress

<sup>35</sup> all retroflex consonants were presented by doubling the IPA symbols /t/ as tt and /d/ as dd (Robert, 2000)

<sup>36</sup> present on in Arabic loan words

<sup>37</sup> /f/ is pronounced as /p/ by Robert, 2000

<sup>38</sup> /x/ is presented with the alternative symbol /k<sup>h</sup>/ and /ɣ/ with /g<sup>h</sup>/ (Robert, 2000)

a lot. Each word has a primary stress which is differently determined for each word but most probably stress falls on the final syllable, first or penultimate syllable of the word (Robert, 2000). So, lexical items can be distinguished on the bases of stress. There are three types of stress i.e. weak, medium and strong. The Pashto speakers use lexical stress to differentiate homograph for getting different meanings (Ijaz, 2002-2003). Stress is also used to change number, tense and gender in Pashto language (as cited in Ijaz, 2002-2003; Comrie, 1987).

### **Vowels**

In Pashto language, according to Din and Rehman, (2011) there are nine vowels but Robert (2000) has claimed seven vowels and according to Ijaz (2002-2003) there are seven short and three long vowels. She said, Pashto speakers randomly use short vowels but the long vowels are only used for pronouncing loan words of Persian and Arabic languages.

In Pashto, the long front close vowel /i/ has a short counterpart /ɪ/ vowel and long back high /u/ vowel has a short counterpart /ʊ/ vowel. The front and back vowels are asymmetrical i.e. there are only two back /u/ and /o/ and two front vowel /i/ and /æ/ vowels. Due to the lesser number of vowels the articulatory space between vowels is very limited (Din & Rehman, 2011).

Due the vowel harmony process, the mid vowel /o/ and /ee/ converted into /u/ and /i/ by raising only when the following syllables contain high vowels and the middle short vowel schwa /e/ converts into /i/ and /u/ vowels if followed by rounded consonants (Robert, 2000).

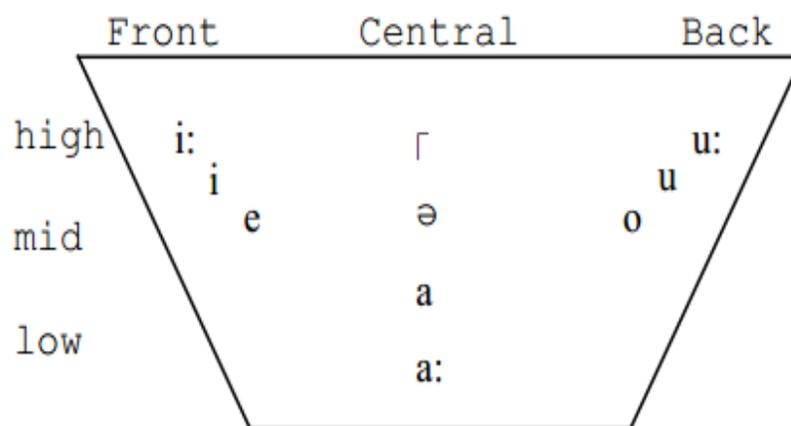

Figure 21: Pashto Vowels (by Ijaz, 2002-2003)

## Summary of Pashto Language

- According to Din and Rehman (2011), Pashto is an East Indo Iranian language and has twenty million speakers in Pakistan, Iran and Afghanistan.
  - It is a provincial language and also the medium of the instruction in Khyber-Pakhtunkhwa.
  - It has five main dialects; Yusuzia, Kandahari Dialect, Middle Tribal Dialect, Central Dialect and the Dialect of Quetta
- According to Robert (2000), It has forty two phonemes;
  - Thirty three consonants
  - Nine vowels

### 2.9.6. Saraiki

Saraiki is called the sister language of Sindhi because Saraiki speaking area was remained the area of Sindh and the spoken dialect of Sindhi language was called “Siroki” means northern. Later in 8<sup>th</sup> century, Saraiki speaking area get separated from Sindh and was called Multan (as cited in Abbas, 2012; Mehr, 1967). In 1818, the ruler of Punjab, Ranjeet Singh attacked and occupied Multan by adding it into Punjab. Punjabi influenced a lot to Saraiki and got mixed with it. Which became the cause of controversy over the isoglosses of both languages i.e. Punjabi linguist claimed that Saraiki is the dialect of Punjabi language and Saraiki linguist claimed that Saraiki is an individual and independent language. But most of the Western linguists accepted it as an independent language (as cited in Abbas, 2012: Jukes, 1900; Grierson 1919; Smirnov, 1975; Shackle 1972, 1976, 2007a, 2007b). The given picture shows the formation of the Saraiki language: (Abbas, 2012).

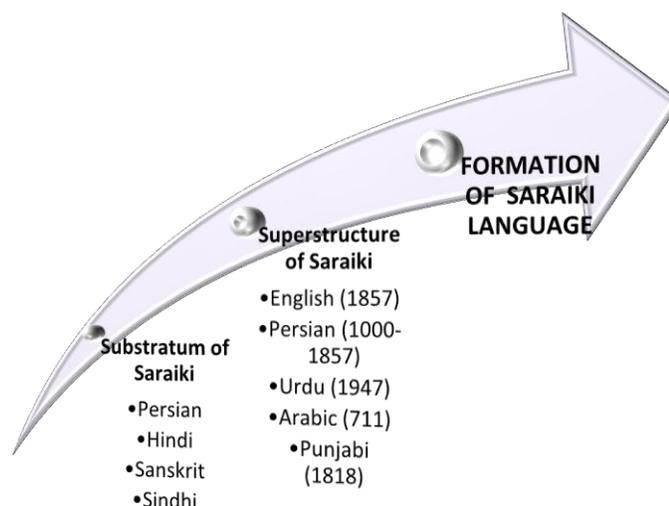

Figure 22: Formation of Saraiki Language

In 1962, the word ‘Saraiki’ is firstly used in the meeting held under the banner of *Bazm-e-Saqafat*, Multan and this variety is sometimes called *Multani* because of the historical significance of Multan. In 1980, Rasoolpuri calls this a ‘pure’ form of Saraiki (Awan, Baseer, & Sheeraz, 2012). The meaning of the word Saraiki has many interpretations by different researchers. The most important is that Saraiki is extracted from the word ‘*Asurki*’ which is extracted from the Saraiki word ‘Surya’ meaning the sun and Asury was the nation who worshipped the sun and ruled in Multan (as cited in Latif, 2006; Ahsan, 1990).

Saraiki belongs to Indo Aryan family and is the language of inhabitants of Indus Valley (Latif, 2006). Since it belongs to the languages of the North Western zone, its dialects bent into Punjabi and Sindhi by showing 85% lexical similarity to Sindhi and 68% with Sansi, Odki and Dhatki (as cited in Latif, 2006; Baart, 2001). Saraiki is an archaic language, found in the Indus civilization i.e. Ddedawar, Harappa, Kot Deji, Multan, Mohenjodaro and Texila (as cited in Latif, 2006; Ahsan 1990). It got the status of

an independent language during the reign of General Zia-ul-Haq in 1981 (as cited in Latif, 2006; Feroz).

Saraiki is a regional language (as cited in Latif, 2006; Gardezi, 1996) and widely spoken in central areas of Pakistan; South Punjab, some parts of Balochistan, Sindh and Khyber-Pakhtunkhwa in Pakistan (Awan et al, 2011). But it is facing an economical competition with dominant languages; Urdu and English. The population census of 1981 treated it as an independent language, spoken by 9.83% of the total population in Pakistan (Rehman T. , 2002). But Wagha (1990) claims that due to some social, political and economical reasons this figure is underestimated. According to Paul (2009) 13,843,106 people speak Saraiki in Pakistan and 20,000 people in India. Haq (1967) claims, in Pakistan the area where Saraiki is being spoken is 48093 sq. miles. It is a spoken language and most of the speakers are unaware of the Saraiki script although it has ancient roots but has no literature (as cited in Latif, 2006).

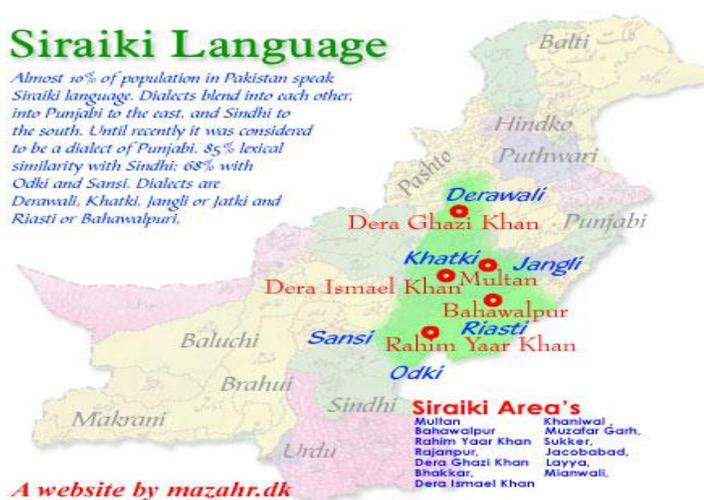

Figure 23: Distribution of Saraiki Language in Pakistan<sup>39</sup>

<sup>39</sup> Retrieved 12-08-13: <http://www.googlemaps>

Saraiki has attracted the attention of foreign researchers including orientalist like George Grierson, E. O. Brian, Christopher Shackel, Trump, Wilson and Jukes. But almost all linguistic works deal with the historical debate of the language. Most of the researches were carried out by the non native people; Mehr (1967) made the first serious attempt to study it. The efforts of Zami (1963, 1970, 1982), Fikri (1970), Mughal (1990, 1996, 2000, 2003), Wagha (1990) were all focused on the study of history, vocabulary and grammar of the language. Since the emergence of Pakistan, the research in the field of Saraiki language has been very slow (Nasir, 2012).

It is considered the mother tongue or the first language for the people of the central Pakistan whereas the second language for the rest of Pakistani population. No other Pakistani language is spoken as frequently as Saraiki is used. In 1976, Rasoolpuri reinforces this idea by accepting that Saraiki language is the only Pakistani language which is spoken and comprehended by all the provinces in Pakistan (Haq, 1967).

### **Phonetic Inventory**

According to Awan et al (2012), Saraiki has six varieties or dialects; Jhangi, Shahpuri, Southern variety, Sindhi variety, Central variety and Northern variety. These varieties are divided on the basis of regions they belong to; Multani, Riasti (Bahawalpuri), Dera Wali, Jhangi, etc. However, all these varieties are given an agreed and collective name i.e. Saraiki. *Central variety* is considered as a standard dialect among all varieties and the speakers of this variety are found in the districts of Multan, Bahawalpur, Muzaffargarh and also in the Northern parts of D. G. Khan.

The total number of Saraiki phonemes are; 94 and not 48, 56 or 58 believed by Shackle, Rasoolpuri and Haq. The problem with their understanding and description is that they ignore the fact that Saraiki monophthongs and diphthongs are separate sounds. It is a syllable time language and has 40 consonants, 23 vowels and 31 diphthongs.

In Saraiki language, there are sixteen plosives and all of these are separate phonemes, not the allophones because they create different words with distinguishing meanings. /t/, /d/, /tʰ/, /dʰ/, /ɳ/, /s/, /z/ are dental sounds and /tʃ/, /dʒ/, /tʃʰ/, /dʒʰ/ are affricate sounds. It has six retroflex sounds i.e. /ɭ/, /ɻ/, /ɭʰ/, /ɻʰ/, /ɳ/, /ɻ/ and two velar sounds /x/ and /ɣ/. It also has one approximant i.e. /j/. But Saraiki has no /θ/ and /ð/ dental sounds. Saraiki has four implosives /ɓ/, /ɗ/, /ɟ/, /ɠ/ but /l/, /r/ are alveolar, /r/ is flap, /m/ is bilabial, /h/ is glotto-velar and /ŋ/ is nasal sounds.

Table 16: *Saraiki Consonantal Inventory (Awan et al., 2011)*

Place Manner	Bilabial	Labio- dental	Dental	Alveolar	Palato Alveolar	Retroflex	Palatal	Velar	Glottal
<b>Plosive</b>	p    b p <sup>h</sup> b <sup>h</sup>		t    d t <sup>h</sup> d <sup>h</sup>			ɭ    ɻ ɭ <sup>h</sup> ɻ <sup>h</sup>		k    g k <sup>h</sup> g <sup>h</sup>	
<b>Affricate</b>					tʃ    dʒ tʃ <sup>h</sup> dʒ <sup>h</sup>				
<b>Nasal</b>	m		ɳ			ɻ		ŋ	
<b>Fricative</b>		f    v	s    z				ʃ	x    ɣ	h
<b>Lateral</b>				l					
<b>Tap/Flap</b>				r		ɻ			
<b>Glides</b>							j		
<b>Implosive</b>	ɓ		ɗ		ɟ			ɠ	

## Vowels

According to Awan et al (2011), there are 23 monophthongs or vowels in Saraiki. It has five long vowels: /i:/, /a:/, /o:/, /e:/, /u:/ and eight short vowels: /i/, /a/, /e/, /ɛ/, /æ/, /ʌ/, /ʊ/, /ɔ/. It also has four long nasal vowels: /ĩ:/, /ã:/, /õ:/, /ẽ:/ and six short nasal vowels i.e. /ũ/, /ã̃/, /õ̃/, /ẽ̃/, /æ̃/, /ɫ̃/. The location of Saraiki short monophthongs is shown in figure 24.

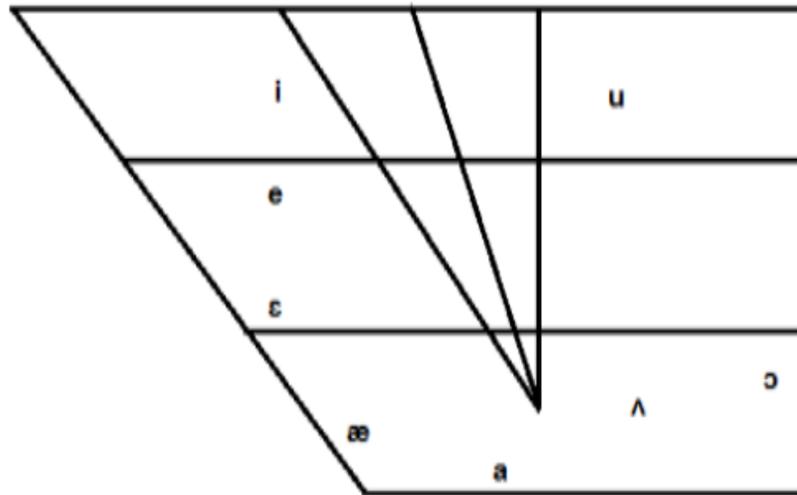

Figure 24: Saraiki Vowels

Table 17: *Saraiki Vowels*

Sr. No.	Oral Vowels	Nasal Vowels
1	ɪ:	ĩ:
2	a:	-
3	o:	õ:
4	e:	ẽ:
5	u:	ũ:
6	i	-
7	a	ã
8	e	ẽ
9	ɛ	-
10	æ:	æ̃
11	ʌ	ã̃
12	u	ũ
13	ɔ	õ

### Diphthongs

According to Awan et al (2012), Saraiki has 31 diphthongs: /ɬi/, /ɔi/, /ui/, /k<sup>h</sup>ui/, /ei/, /æ/, /ɛ/, /ie/, /oe/, /ue/, /ao/, /ʌo/, /eo/, /io/, /æɛ/, /au/, /iu/, /ea/, /ua/, /iʌ/, /ʌ /, /aĩ/, /uĩ/, /uẽ/, /iõ/, /aũ /, /iũ/, /eũ/, /ʌũ/, /uã/, /ɟuã/, /eã/, /iã/. It does not have /əʊ/ and /ai/ diphthong and no diphthong ends at /ə/ (because it is syllable time language).

## Syllable Templates

According to Awan et al (2012), Saraiki is a syllable time language because all syllables occur at regular interval of time. There is no vowel reduction in Saraiki because of the syllable timing. Saraiki has 10 syllable templates;

Table 18: *Saraiki Syllable Templates*

<b>Sr. no.</b>	<b>Saraiki Syllable Templates</b>

## Summary of Saraiki Language

- Saraiki is an Indo Aryan language and is a regional language in Pakistan (Latif, 2006).
- It recognized as an independent language in the government of General Zia ul Haq (as cited in Latif, 2006; Feroz).

- It has six dialects; Central variety, Jhangi, Shahpuri, Southern variety, Sindhi variety, and Northern variety.
- According to Awan et al (2012), Saraiki is a syllable time language. It has ten syllable templates and has ninety four phonemes;
  - Forty consonants
  - Twenty three vowels
  - Thirty one diphthongs

## Comparison of Consonantal Inventories by Using Literature Review

As a first step; comparison of consonantal inventories (of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki) has been done with the help of literature review. The first step is further divided into two steps by comparing the differences or gaps in the places and manners of articulation.

### 2.10. Step I: Analysis of Phonetic Inventories on the basis of Place of Articulation

According to Skandera and Burleigh (2005) almost all consonantal sounds are produced with the obstruction of the pulmonic air stream in pharynx, vocal or nasal tract. The speech organs that are basically involved in the production of a particular speech sound are most important in terms of place of articulation. A consonantal sound is produced with the contact of the lower, actively mobile speech organs to upper, passively immobile speech organs. **Labial** sounds are produced with the lips' movement and form a large group in consonantal inventory. All dental, alveolar, post-alveolar and retroflex sounds are produced with the involvement of the tongue tip therefore are also called '**apical sounds**'. The palatal, the velar and the uvular sounds are also called '**dorsal sounds**' because all these sounds use body of the tongue. Almost all these consonants are discussed here in detail;

### 2.10.1. Bilabials

The sounds produced with the contact of lips by creating obstruction of the air stream in the oral tract (Skandera & Burleigh, 2005). /p/, /b/, /m/ are bilabial sounds in Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. /p<sup>h</sup>/ and /b<sup>h</sup>/ are bilabial aspirated stops found in Urdu, Sindhi and Saraiki languages, Punjabi has only voiceless aspirated stop /p<sup>h</sup>/. Bilabial fricative /f/ is only present in Balochi and Pashto languages. Punjabi, Balochi and Pashto have bilabial glide /w/. Only Sindhi and Saraiki have bilabial ingressive stop /ɓ/. Bilabial aspirated /m<sup>h</sup>/ is only present in Urdu language but in rare cases.

Table 19: Comparison of Bilabial Stops among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>

<b>Fricative</b>				(f)	(f)	
<b>Nasal</b>	m m <sup>h</sup>	m	m	m	m	m
<b>Glide</b>		w		w	w	
<b>Implosive</b>			ɓ			ɓ

### 2.10.2. Labiodentals

The sounds produced with the obstruction of air stream by the contact of lower lip against the upper teeth are called labiodental sounds (Skandera & Burleigh, 2005). /f/ and /v/ are articulated as labiodental fricative in Urdu, Punjabi and Saraiki. /w/ is labiodental glide in Urdu language.

Table 20: Comparison of Labiodentals among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>

<b>Stop</b>						
<b>Fricative</b>	f v	f v				f v
<b>Glide</b>	(w)					

### 2.10.3. Dental/interdentals

Dental sounds are produced with the partial or complete contact of tongue tip with the back of the upper teeth (Skandera & Burleigh, 2005). /t̪/, /d̪/, /t̪ʰ/, /d̪ʰ/ are articulated as dental stops in Urdu, Sindhi and Saraiki, /t̪/, /d̪/ are dental stops in Punjabi, Sindhi, Balochi, Pashto but Punjabi has only voiceless dental stop /t̪ʰ/. Balochi and Pashto have no aspirated labiodental stops. Dental implosive /ɖ/ is present only in Saraiki. /n/ is dental nasal in Urdu, Punjabi, Balochi and Saraiki languages. /s/ and /z/ are dental fricative in Balochi and Saraiki but are spirants in Pashto. Aspirated dental nasal /nʰ/ is present only in Urdu language. Lateral phoneme /l/ is dento-alveolar sound in Balochi while dento-lateral in Pashto language. /r/ is dento-alveolar flap in Balochi and Pashto.

Table 21: Comparison of Dentals among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi Dental</b>	<b>Pashto</b>	<b>Saraiki</b>

<b>Nasal</b>	n    nʰ			n		ɳ
<b>Spirants</b>					s    z	
<b>Lateral</b>				l	l	
<b>Flap</b>				r	r	
<b>Implosive</b>						ɖ

### 2.10.4. Alveolar

The alveolar sounds produced when the tip of the tongue is coming near or touches the bony alveolar ridge area (Skandera & Burleigh, 2005). /n/ is alveolar voiced nasal in Punjabi and Sindhi. /s/ and /z/ are alveolar fricative in Urdu, Punjabi, Sindhi and Pashto languages. /l/ is alveo-lateral in Urdu and Saraiki, dento-lateral in Punjabi and dento-alveo-lateral in Balochi but is voiced alveolar tap in Pashto language. /r/ is voiced alveolar glide in Pashto but is alveolar flap/tap in Urdu, Punjabi, Balochi and Saraiki languages.

Table 22: Comparison of Alveolar Consonants among Six Languages

<b>Nasal</b>		n	n			
<b>Lateral</b>	l l <sup>h</sup>	l				l
<b>Tap/Flap</b>		r				r
<b>Glide</b>					r	

### 2.10.5. Post-alveolar

When the tip of the tongue reaches just behind the alveolar ridge, the post alveolar sounds are produced (Skandera & Burleigh, 2005). /tʃ<sup>h</sup>/, /dʒ<sup>h</sup>/ are post alveolar aspirated fricative in Sindhi. /ʃ/ is post alveolar affricate in Sindhi, post alveolar affricates in Pashto language. Post alveolar Implosive /ɟ/ is present only in Sindhi and Saraiki languages. In Pashto language, the speakers of Northwest and Northeastern dialects pronounce /s̃/ and /z̃/ as fricatives /s/ and /z/ while the speakers of Southwestern and Southeastern groups pronounce as affricates /tʃ/ and /dʒ/ respectively.

Table 23: Comparison of Post Alveolar Consonants among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>
	<b>Post - Alveolar</b>	<b>post- alveolar</b>	<b>Post- alveolar</b>	<b>Post- alveolar</b>	<b>Palato- Alveolar</b>	<b>Palato Alveolar</b>

<b>Affricates</b>			ʃ		c̃      j̃	tʃ      dʒ tʃ <sup>h</sup> dʒ <sup>h</sup>
<b>Spirants</b>					s̃      z̃	
<b>Implosive</b>			ɟ			ɟ

### 2.10.6. Retroflex

Retroflex sounds are produced with the curling back of the tongue tip towards the hard palate (Skandera & Burleigh, 2005). /ʈ/ and /ɖ/ are retroflex stops in Urdu, Punjabi, Balochi (with alternative symbols /ʈ/, /ɖ/ respectively) Pashto and Saraiki but in Sindhi are retroflex affricates. /ʈʰ/, /ɖʰ/ are aspirated retroflex stops in Urdu and Saraiki and are retroflex affricates in Sindhi but Punjabi has only voiceless aspirated retroflex stop /ʈʰ/. Retroflex implosive stop /ɗ/ is present only in Sindhi language. Retroflex tap/flap /ɽ/ is present in Urdu, Punjabi, Balochi (with alternative symbol /ɽ/) and Saraiki but is retroflex glide in Pashto language. But the aspirated retroflex tap /ʈʰ/ is present only in Urdu but in rare cases. Retroflex nasal /ɳ/ is present in Punjabi, Sindhi, Pashto (with an alternative symbol /ɳ/) and Saraiki. /ɭ/ is retroflex lateral in Punjabi and Sindhi languages. /ɽ/ is retroflex trill in Sindhi language.

In Pashto language, /x̌/ and /ǧ/ are spirants phonemes means, these sounds are pronounced differently in different dialects. As the speakers of North western group pronounce them as /f/ and /ɣ̌/ or ž/, the speakers of Northeastern group pronounce them as /x/ or k<sup>h</sup> / and /g/ while the speakers of South western and South Eastern group pronounce these sounds as /tʃ/ and /dʒ/ respectively (Elfenbein, 1997).

Table 24: *Comparison of Retroflex among Six Languages*

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>

<b>Lateral</b>		ɭ	l			
<b>Tap/Flap</b>	ɽ ɽʰ	ɽ		ɽ̣		ɽ
<b>Glide</b>					ɽ̣	
<b>Trill</b>			r			

### 2.10.7. Palatal

Palate is divided into two parts i.e. soft palate and hard palate. Hard palate is also called “*roof of the mouth*” (Roach, 1998, pp. 9) and the sounds produced with the contact of the tongue body to the hard palate are called palatal sounds. Palato alveolar sounds are produced when the tip of the tongue touches the alveolar ridge and the blade of the tongue is raised towards the hard palate simultaneously (Skandera & Burleigh, 2005).

/tʃ/ and /dʒ/ are palatal affricates in Punjabi and Balochi. /tʃʰ/ is voiceless aspirated palatal affricate in Saraiki. The sound of /ʃ/ is palatal fricative in Urdu, Punjabi, Saraiki and prepalatal palatal fricative in Balochi (with alternative symbol /š/) and /ʒ/ is voiced palatal fricative in Urdu and prepalatal palatal voiced fricative in Balochi (with alternative symbol /ž/). The sound /j/ is palatal glide in Urdu, Pashto and Balochi (with alternative symbol /y/) palatal affricate in Sindhi and palatal approximant in Saraiki but is voiced in Sindhi and Pashto languages. Sindhi language has another voiced palatal nasal /ɲ/.

Table 25: *Comparison of Palatals among Six Languages*

	<b>Urdu Palatal</b>	<b>Punjabi Palatal</b>	<b>Sindhi Palatal</b>	<b>Balochi Prepalat al palatal</b>	<b>Pashto Palatal</b>	<b>Saraiki Palatal</b>

<b>Nasal</b>			ɲ			
<b>Trill</b>	r    rʰ					
<b>Approximant</b>	j	j		y	j    j	j

### 2.10.8. Velar

Velum or soft palate is an important oral organ which allows the air to pass through the mouth and nose (Roach, 1998, pp. 9). When the back of the tongue comes in contact with the lower side of the velum or soft palate, velar sounds are produced (Roach, 1998, pp. 9; Skandera & Burleigh, 2005).

/j/ is velar glide in Punjabi. /k/, /g/ are velar stops in Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages. /k<sup>h</sup> /, /g<sup>h</sup>/ are aspirated velar stops in Urdu, Sindhi and Saraiki but Punjabi has only /k<sup>h</sup> /voiceless aspirated velar stop. Sindhi and Saraiki also have implosive velar stop /ɠ/. The sounds of /x/ and /ɣ/ are velar fricatives in Punjabi, Balochi (/ɣ/ with alternative symbol /ḡ/), Pashto and Saraiki. Velar nasal /ŋ/ is also present in Urdu, Punjabi, Sindhi, Pashto and Saraiki languages.

Table 26: Comparison of Velars among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>
	<b>Velar</b>	<b>Velar</b>	<b>Velar</b>	<b>Velar</b>	<b>Velar</b>	<b>Velar</b>

<b>Glide</b>		j				
<b>Implosive</b>			ɠ			ɠ

<sup>40</sup> Velar nasal /ŋ/ has reported only by Karamat (2010)

### 2.10.9. Uvular

The uvular sounds are produced by moving the root of the tongue near the uvula (Skandera & Burleigh, 2005). /q/ is uvular stop only in Urdu and Pashto. The sounds of /x/, /ɣ/ are uvular fricatives in Urdu (/ɣ/ with alternative symbol /g/) and uvular affricates in Sindhi.

Table 27: Comparison of Uvular Consonants among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>
	<b>Uvular</b>	<b>Uvular</b>	<b>Uvular</b>	<b>Uvular</b>	<b>Uvular</b>	<b>Uvular</b>
<b>Stop</b>	q				q	
<b>Fricative</b>	x					
<b>Affricate</b>			x      ɣ			

### 2.10.10. Glottal

The glottal sounds are articulated in larynx when the air passed through the glottis (Skandera & Burleigh, 2005). All six languages, Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki have glottal fricative /h/ but only Sindhi language has voiced and voiceless /h/.

Table 28: Comparison of Glottal Consonants among Six Languages

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>
	<b>Glottal</b>	<b>Glottal</b>	<b>Glottal</b>	<b>Glottal</b>	<b>Glottal</b>	<b>Glottal</b>
<b>Fricative</b>	h	h	h      h	h	h	h

## 2.11. Step II: Analysis of Phonetic Inventories on the basis of Manner of Articulation

According to Skandera and Burleigh, (2005) the manner of articulation refers the type of the closure by the speech organs. There are eight manners of articulation that use an egressive pulmonic air stream mechanism i.e. plosives, fricatives, affricates, nasals, laterals, trills, tap or flap and approximants. Along with manner of articulation continuant and non continuant difference is another terminological distinction for the analysis of the consonants. *Non-continuants* sounds are produced with the complete closure of the speech organs. Therefore plosives and affricates are non continuant sounds because are pronounced with the complete closure of oral or nasal tract. And all other sounds including nasal sounds are produced with the partial closure of the speech organs therefore are called *continuants*. Lateral sounds are also referred as *frictionless continuants* because there is no audible friction.

### 2.11.1. Stops/Plosives

The consonants which are produced by creating a short stricture (closure phase) by compressing the air in the mouth (hold phase) for a short time period than after holding (release phase) the air for a short time, the compressed air is released with the plosion (post release phase) are called stops or plosives. There are three types of plosives; bilabial plosives (/p/, /b/) palato alveolar plosives (/t/ and /d/) and velar plosives (/k/ and /g/) in English (Roach, 1998; Skandera & Burleigh, 2005).

/p<sup>h</sup>/ and /b<sup>h</sup>/ bilabial aspirated stops in Urdu, Sindhi and Saraiki languages, Punjabi has only voiceless bilabial stop /p<sup>h</sup>/. But the phonemic inventory of Urdu language has a large number of stop consonants than other languages such as /p/, /b/, /p<sup>h</sup>/, /b<sup>h</sup>/, /t/, /t<sup>h</sup>/, /d/, /d<sup>h</sup>/, etc. Balochi and Pashto have bilabial glide stop /w/. Only Sindhi and

Saraiki have bilabial ingressive stop /β/. The sounds of /t/ and /d/ are dental stops in Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki, /tʰ/ and /dʰ/ are aspirated dental stops present in Sindhi and Saraiki but Punjabi has only voiceless dental stop /tʰ/. Balochi and Pashto have no aspirated labiodental stops. /t/ and /d/ are retroflex stop in Urdu, Punjabi, Balochi (with alternative symbols /ɽ/ and /ɖ/ respectively) Pashto and Saraiki. The sounds of /tʰɽ/ and /dʰɽ/ are aspirated retroflex stops in Urdu and Saraiki but Punjabi has only /tʰɽ/ voiceless aspirated retroflex stop. Retroflex implosive stop /ɖ/ is present only in Sindhi language. /k/ and /g/ are velar stops in all six languages; Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. /kʰ/, /gʰ/ are aspirated velar stops in Urdu, Sindhi and Saraiki but Punjabi has only /kʰ/ voiceless aspirated velar stop. Sindhi and Saraiki also have implosive velar stop /ɠ/. The uvular stop /q/ and glottal stop /ʔ/ are only present in Urdu and Pashto languages.

Table 29: Comparison of Stops among Six Languages

	Urdu	Punjabi	Sindhi	Balochi	Pashto	Saraiki

<b>Uvular Stop</b>	q				q	
<b>Glottal Stop</b>	ʔ				ʔ	

### 2.11.2. Fricatives

The fricatives are produced with the release of air by a narrow passage with hissing sound and are also called *continuants* because one can continue to produce a fricative consonant without any interruption as long as one can sustain breath (Roach, 1998, pp. 47). According to Skandera and Burleigh (2005), in English, there are nine fricatives: /f/, /v/, /θ /, /ð/, /s/, /z/, /ʃ/, /ʒ/ and /h/. These fricative sounds are subdivided into two categories i.e. slit fricatives and groove fricatives depending on the width and depth of the tongue respectively. In English /f/, /v/, /θ /, /ð/ and /h/ are called *slit fricatives* because they have no point of narrowing and /s/, /z/, /ʃ/, /ʒ/ are also called *groove fricatives* by forming a groove along the tongue. Groove fricatives are pronounced with more intensity than slit fricatives therefore also called *sibilants*.

/f/ is articulated as labiodental fricative in Urdu, Punjabi and Saraiki but is bilabial fricative in Pashto and Balochi. /v/ is labiodental fricative in Saraiki language. /ʃ/ and /dʒ/ are post alveolar fricative in Sindhi. /tʃ<sup>h</sup>/ and /dʒ<sup>h</sup>/ are post alveolar aspirated fricative in Sindhi, /ʃ/ is palatal fricative in Urdu, Punjabi, Saraiki and prepalatal palatal fricative in Balochi (with alternative symbol /š/) but is post alveolar fricative in Pashto. /ʒ/ is voiced palatal fricative in Urdu and prepalatal palatal voiced fricative in Balochi (with alternative symbol /ž/). The sounds of /x/ and /χ/ are uvular fricatives in Urdu (/χ/ with alternative symbol /q/), velar fricatives in Punjabi, Balochi (/χ/ with alternative symbol /ğ/), Pashto and Saraiki. /s/ and /z/ are alveolar fricative in Urdu, Sindhi and Pashto but are dental fricative in Punjabi, Balochi and Saraiki languages. /h/ is glottal fricative in all six languages (Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki) but Sindhi language has voiced glottal fricative /h/.

Table 30: Comparison of Fricatives among Six Languages

<b>Palatal Fricative</b>	ʃ ʒ	ʃ		š ž		ʃ

#### 2.11.4. Nasals

Nasal consonants are produced when air passes through the nasal tract by lowering the soft palate and creating a stricture in the oral cavity and the stricture may occur at three places i.e. bilabial stricture produces /m/, alveolar /n/ and velar /ŋ/ (Roach, 1998; Skandera & Burleigh, 2005).

The phoneme /m/ is present in all the six languages i.e. Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. /n/ is dental nasal in Urdu, Punjabi, Balochi and Saraiki, /n/ is alveolar voiced nasal in Sindhi. Retroflex nasal /ŋ/ is present only in Punjabi, Sindhi, Pashto (with an alternative symbol /ŋ/) and Saraiki. /ŋ/ is voiced in Sindhi and Pashto languages only. Sindhi, Pashto and Saraiki also have velar nasal /ŋ/. Sindhi language has another voiced palatal nasal /ɲ/.

Table 32: *Comparison of Nasals among Six Languages*

	<b>Urdu</b>	<b>Punjabi</b>	<b>Sindhi</b>	<b>Balochi</b>	<b>Pashto</b>	<b>Saraiki</b>
<b>Bilabial Nasal</b>	m	m	m	m	m	m
<b>Dental Nasal</b>	n	n		n		ɳ
<b>Alveolar Nasal</b>			n			
<b>Retroflex Nasal</b>		ɳ	ɳ		ŋ	ɳ
<b>Palatal Nasal</b>			ɲ			
<b>Nasal Velar</b>			ŋ		ŋ	ŋ

### 2.11.5. Laterals

The lateral consonant /l/ is produced when the center of the tongue and alveolar ridge are in close contact by stopping the air passage than air releases from the sides of the tongue (Roach, 1998, pp. 58; Skandera & Burleigh, 2005). /l/ is an alveo-lateral in Urdu and Saraiki. /l/ is dento lateral in Punjabi, dento alveo lateral in Balochi and voiced alveolar tap in Pashto. Retroflex lateral /ɭ/ is only present in Punjabi and Sindhi languages. Aspirated lateral /l<sup>h</sup>/ is observed in Urdu only.

Table 33: *Comparison of Laterals among Six Languages*

	Urdu	Punjabi	Sindhi	Balochi	Pashto	Saraiki
<b>Dental Lateral</b>		l		l		
<b>Alveolar Lateral</b>	l    l <sup>h</sup>				l	l
<b>Retroflex Lateral</b>		ɭ	ɭ			

### 2.11.6. Post alveolar Approximants

Post alveolar approximants are produced when articulators come close to each other without touching and releasing air to produce vowel like sounds and these are also called semi vowels, glides or approximants (Roach, 1998; pp. 59 & 60). But the gap between the articulators is larger than the fricatives (Skandera & Burleigh, 2005).

/j/ is palatal glide in Urdu, Pashto, Balochi (with alternative symbol /y/), palatal approximant in Saraiki and velar glide in Punjabi. /ɽ/ is retroflex glide in Pashto. /v/ is labiodental glide in Urdu. /r/ is voiced glide in Pashto. Post alveolar Implosive /ɟ/ is present only in Sindhi and Saraiki languages.

Table 34: *Comparison of Approximants among Six Languages*

	Urdu	Punjabi	Sindhi	Balochi	Pashto	Saraiki
<b>Bilabial Approximant</b>		v		w	w	
<b>Labiodental Approximant</b>	v					
<b>Alveolar approximant</b>					r	
<b>Retroflex approximant</b>					ɽ	

### 2.11.7. Trills/Rolls

Trill sound is produced when one articulator vibrates against another by forming an intermediate closure of speech organs in the vocal tract (Skandera & Burleigh, 2005).

/r/ is retroflex trill in Sindhi language.

Table 35: Comparison of Trills Consonants among Six Languages

	Urdu	Punjabi	Sindhi	Balochi	Pashto	Saraiki
<b>Retroflex Trill</b>			r			

### 2.11.8. Tap/Flaps

Tap/Flaps are produced with the single flap (touch) of the tongue to the alveolar ridge (Skandera & Burleigh, 2005). /r/ is flap in Urdu, Punjabi, Balochi and Saraiki.

Retroflex tap /ɽ/ is present in Urdu, Punjabi, Balochi (with alternative symbol /ɽ/) and Saraiki language but the aspirated retroflex tap /ɽʰ/ is rarely present only in Urdu.

Table 36: Comparison of Flap/Taps Consonants among Six Languages

	Urdu	Punjabi	Sindhi	Balochi	Pashto	Saraiki
<b>Alveolar Tap/Flap</b>	r					r
<b>Dental Flap</b>		r		r		
<b>Retroflex Tap/Flap</b>	ɽ    ɽʰ	ɽ		ɽ		ɽ

The literature based comparison of the consonantal inventories of six major languages show;

- There are nine redundant alphabetical symbols in all six phonemic inventories of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. Most of these phonemes are borrowed from Persian and Arabic languages e.g. /s/ س ص ث, /z/ ذ ز ظ, /t/ ط, and /ʔ/ ع.
- In all six languages, there is large number of stop consonants in phonetic inventories than any other consonant. But among all six languages, Urdu language has a large number of stops.
- Regardless of other languages, Punjabi has no voiced aspirated stops but has only voiceless aspirated stops like /tʰ/, /tʰ/, etc. But Balochi and Pashto phonetic inventories have no aspirated stops.
- Sindhi language has a number of affricates among all six languages.
- There is no glide or approximant sound in Sindhi language.
- Only Sindhi language has trill /r/ sound.
- All six languages have glottal stop /h/ but only Sindhi language has both voiced and voiceless glottal stop /h/.
- Only Sindhi and Saraiki have ingressive/implosive sounds like /b/, /g/ etc.
- Retroflex nasal /ŋ/ is present only in Punjabi, Sindhi, Pashto (with an alternative symbol /ŋ/) and Saraiki. Sindhi, Pashto and Saraiki also have velar nasal /ŋ/. Sindhi language has another voiced palatal nasal /ɲ/.

The literature review is a brief report on:

- The origin, emerging socio political threats, geographical locations and the number of speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki in Pakistan and all over the world.
- The phonetic inventories of all these six languages i.e. Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki.
- The articulatory classification and description of the consonants and vowels of these languages.
- The phonetic similarities and differences among the inventories of these languages.
- The phonemic importance of these languages.
- The identification of the sounds of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages.
- The confused, redundant or interchanged sounds have also been discussed.

## **CHAPTER 3**

### **METHODOLOGY**

This research is based on quantitative methodology for analyzing accent variations in Pakistani Urdu. The phonetic inventories of six languages have been analyzed for finding out the similarities and gaps of segmental features of Corner vowels.

#### **3.1. Nature of the Study**

The research is exploratory in its nature and it has been designed to investigate the accent variations of Urdu language in Pakistan.

#### **3.2. Population**

Male and female speakers of the six majorly spoken languages in Pakistan

#### **3.3. Sampling**

30 speakers from each of the six languages (Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki) have been selected randomly as a sample.

#### **3.4. Instrumentation**

##### **3.4.1. Instrument**

Data has been collected by online telephone or mobile calls. PRAAT software (a package for analysis of speech in phonetics) has been used for analyzing the acoustical spectral distances by measuring F1, F2 differences. By using the recordings, perceptual analysis (accent identification) has been conducted based on vowels for comprehending different accents.

### **3.5. Corpus**

The list of 139 districts' names of Pakistan has been selected as a corpus or vocabulary (list is also attached). The reason behind the selection of the list is; the district names are language independent and equally intelligible among the speakers of all six languages.

### **3.6. Data**

720 recordings (30 speakers x 6 languages x 4 corner vowels = 720 utterances) have been used for analyzing the vowels (which are available through the data). All these vowels arising from Urdu L2 gap, would find out pair wise and group wise comparison.

### **3.7. Data Analysis**

The data analysis has been conducted on the acoustic phonetic analysis of the vocalic inventories.

## Word List Used for Data Collection and Analysis

## **CHAPTER 4**

### **DATA ANALYSIS & RESULTS**

The data analysis of vocalic inventories has been conducted in PRAAT. The acoustic phonetic analysis of corner vowels (uttered by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages) has been conducted for finding out the accent variation in Pakistani Urdu language.

#### **4. Acoustic Analysis of Vowels**

Phonetically, the vowels sounds are produced without any obstruction of the air in oral or nasal tract and phonologically vowels occupy the central position in the syllable (Skandera & Burleigh, 2005). According to Ladefoged, vowels are produced without causing friction in the oral tract. In comparison with the consonant sounds, vowel sounds are difficult to study and required more attention than consonants (as cited in Kerio, 2010; Kent, 2002; Moore, 2003).

In the present research, only the characteristics of vowels have been investigated to identify the accents of six major languages; Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki in Pakistan. The 139 district names of Pakistan have been used as a speech corpus (for details see Chapter no. 3). This corpus covered all the vowels in the six languages. The corpus was recorded by male and female native speakers with ages varying from 18 to 40 years old. The speakers' distribution in each accent is listed in table no. 38.

Table 37: *Speaker Distribution in each Accent*

Accents	I_I		A_E		A_A		U_U	
	Male	Female	Male	Female	Male	Female	Male	Female
<b>Urdu</b>	22	8	11	9	17	13	14	16
<b>Punjabi</b>	17	13	16	4	17	13	22	8
<b>Sindhi</b>	12	18	10	8	12	18	7	23
<b>Balochi</b>	15	5	8	2	17	13	21	2
<b>Pashto</b>	27	3	20	7	25	5	27	3
<b>Saraiki</b>	17	13	16	11	17	13	18	12

The speech corpus has been recorded over telephone or mobile channel at 8000Hz from the students of the different universities in Pakistan with random background noise. For the experiment, the four corner vowels<sup>41</sup> /i:/, /æ:/, /a:/ and /u:/ have been used as fixed reference points for the description of other vowels in the vocalic inventories. The vowel data used for this study is given in table 39.

Table 38: *Accent Variation among Six Languages*

Accents	I_I (i:)	A_E (æ:)	A_A (a:)	U_U (u:)
<b>Urdu</b>	30	20	30	30
<b>Punjabi</b>	30	20	30	30
<b>Sindhi</b>	30	18	30	30
<b>Balochi</b>	20	10	30	23
<b>Pashto</b>	30	27	30	30
<b>Saraiki</b>	30	27	30	30

<sup>41</sup> According to Oxford Urdu-English Dictionary 2013, duration mark /:/ has been used to differentiate between a long vowel and a short vowel

Formants are sensitive features of a (Chinese) language (Stantic & Jo, 2012). So in our work, we use formants F1, F2 to classify the six major accents of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages in Pakistan. Formants have been manually calculated by using PRAAT software. After normalizing the data, the mean vector for each vowel accent have been computed. Each mean value represents an individual language accent of a specific vowel. Then the distance between two accents of a vowel has been computed by using mean vectors of these accents. And for confirming the results, one way ANOVA statistical analysis has been done by using SPSS software (for details see APPENDIX E).

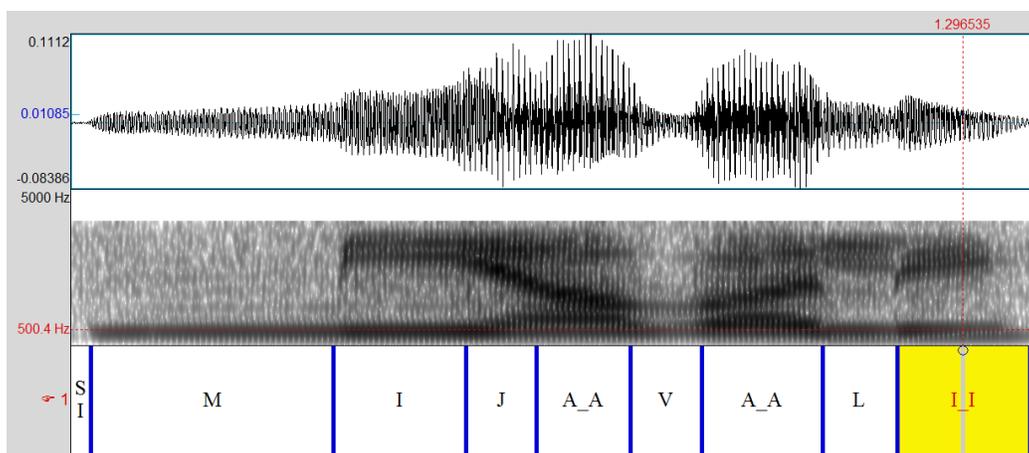

The accent variation among six major languages; Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki has been measured by taking frequencies. In the first step the wave files have been trimmed by excluding background noise from the required voiced signals. In the second step the spectrogram of vowel (districts' names) utterances have been computed and F1, F2 frequencies of the vowels have been marked manually by viewing and measuring spectral slices. In an utterance, formants are usually present in all voiced phonemes such as vowels, approximants and nasals but formants are stable and strong in vowels over the time (as cited in Keerio, 2010; Moore 2003). Urdu formant frequencies can be defined within these ranges; F1 ranges between 200-700 Hz and F2 ranges between 1100-2400 Hz for an adult speaker.

The used symbols for vowels are similar in different languages but their properties are not identical. So, the reference point is useful despite of the similar transcription. Therefore, the phonetics system allowed the languages to describe the vowels with relation to the acoustic properties despite the height of the tongue

(McCombs, 2006) but vowel formants are more dependent on lips movement (Hillenbrand, Getty, Clark, & Michael, 1995). In this study, the acoustic properties of corner vowels in Urdu have been analyzed by keeping in mind the above mentioned properties.

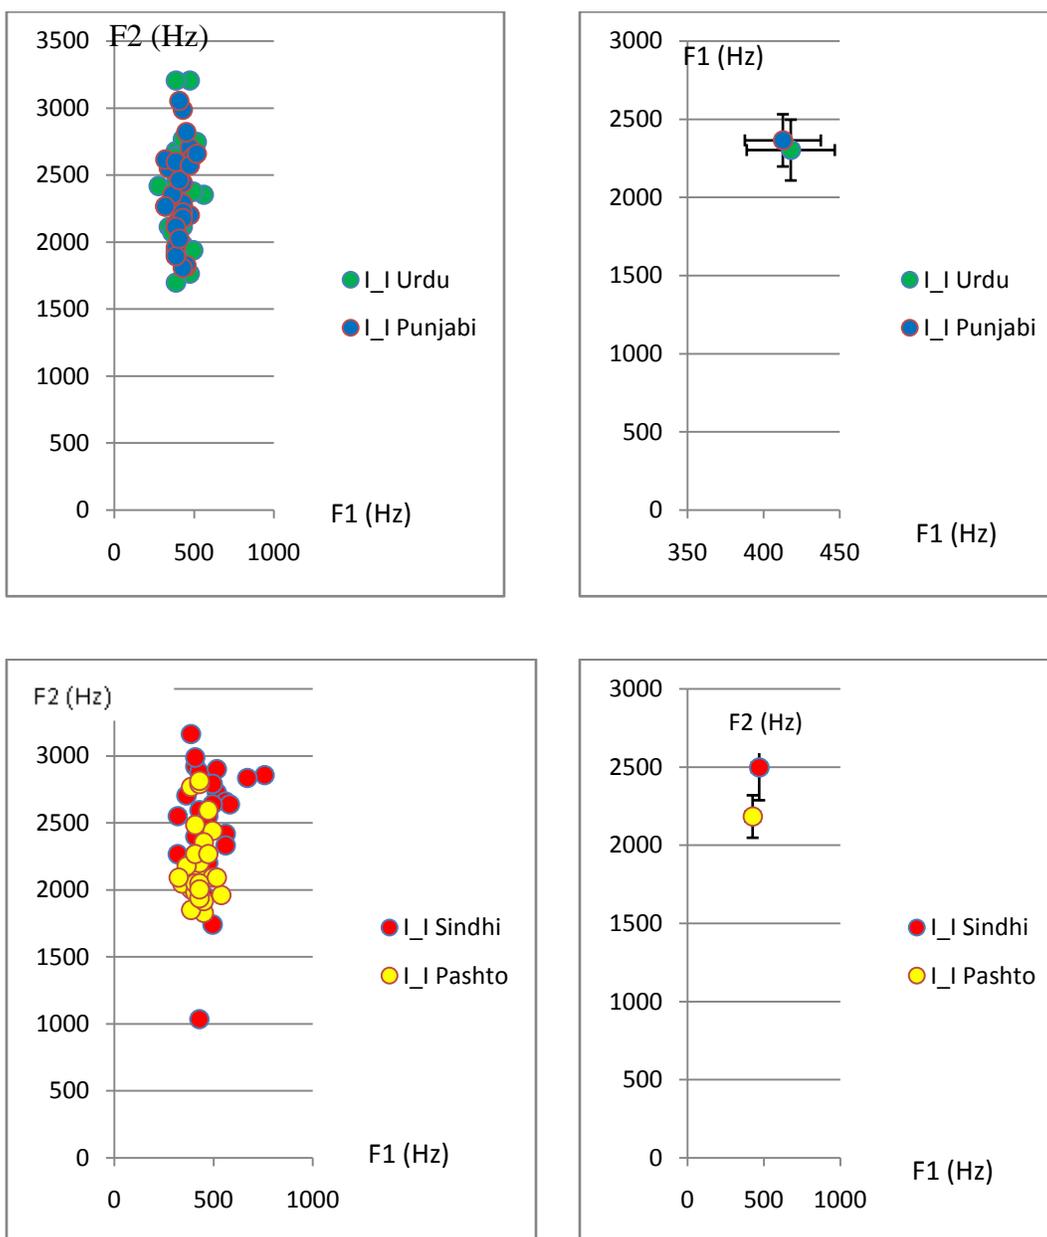

#### 4.1. Acoustic Analysis of I\_I (i:) Vowels

/i:/ vowel is produced when the tongue pushes forward by minimizing the gap between the tongue body and the palate but lips remain neutral for the articulation (Skandera & Burleigh, 2005). In Urdu language, /i:/ vowel has lower F1 and higher F2 values (200-2400 Hz) than /a:/ vowel.

The recorded data was processed in PRAAT software. The data is based on the F1, F2 values of /i:/ vowels. For the understanding of the data variation cluster graphs have been made which show the similar as well as contrastive behavior of different vowels uttered by the speakers of six languages. These graphical representations show that frequencies of vowels vary from each other but some pair wise comparisons show more contrastive behavior than the other. Few of them are elaborated here;

### Pair wise Comparison of I\_I Vowels Uttered by Different Language Speakers

The pair wise comparison shows rate of variation in the formant frequencies (F1, F2) among the utterances from the speakers of the different languages. The pair wise comparison of I\_I vowel uttered by Urdu and Punjabi speakers shows less variation than the I\_I vowel uttered by Sindhi and Pashto speakers.

Figure 25: shows the group wise comparison of the mean and standard deviation of (the long vowel /i:/) I\_I uttered by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages. This group wise comparison shows that the formant frequency values of I\_I vowel uttered by the Balochi speakers are drastically different from the formant frequencies of I\_I vowel uttered by the speakers of Sindhi, Punjabi, Urdu and Saraiki but also shows difference from the formant frequencies of I\_I vowels uttered by Pashto speakers.

### Group wise Comparison of I\_I Vowels

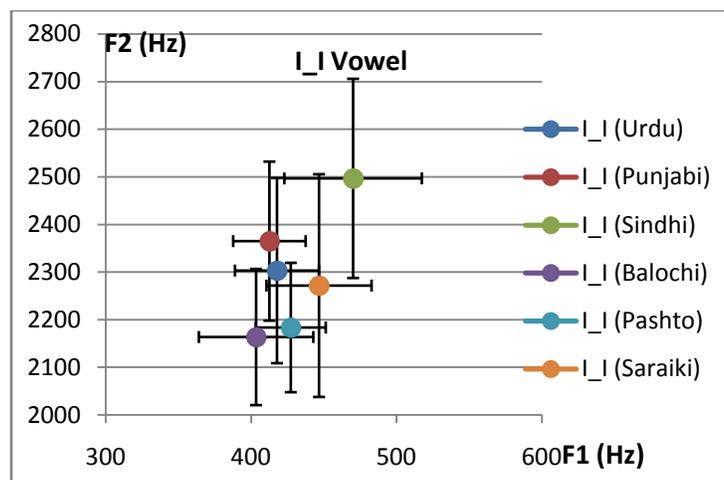

Figure 25: Mean & St. Deviation of /i:/ Vowel

ANOVA test has been run for the verification of the results.

### Statistical Analysis of I\_I (i:) Vowel

		Sindhi	.769			Sindhi	.184
Balochi		.245	Balochi	.916			
Pashto		.880	Pashto	.942			

Table 39: *Difference among /i:/ Vowels*

<b>Significant Values</b>		
<b>Accents</b>	<b>F1</b>	<b>F2</b>
<b>Urdu- Sindhi</b>	0.039	---
<b>Punjabi- Sindhi</b>	0.017	---
<b>Sindhi-Balochi</b>	0.011	.027
<b>Sindhi-Pashto</b>	---	.017

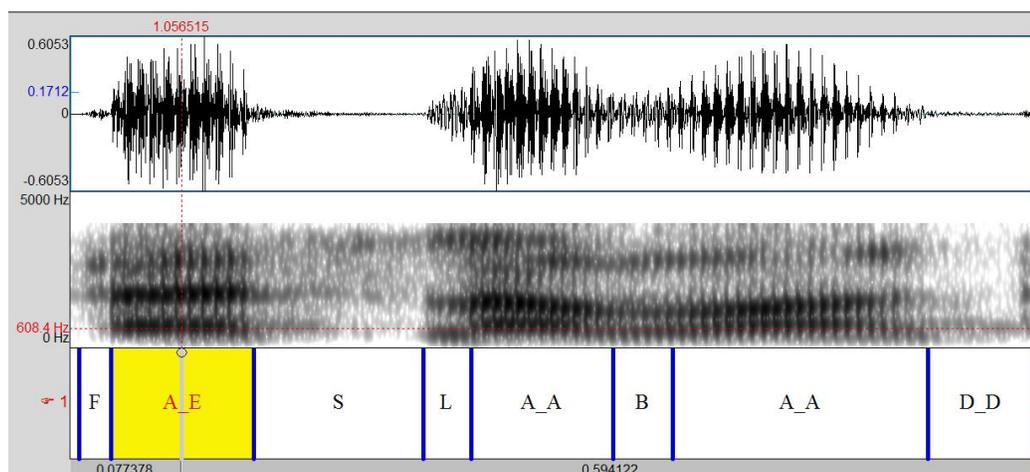

One way ANOVA test was run to determine, if there was any significant difference in I\_I vowel accent (F1, F2) among the six groups of languages. There were no outliers and the data was normally distributed for each group and assessed by the Tukey post hoc test [ $p < .05$ ]. There was statistically significant difference among the groups as determined by one way ANOVA [ $F(5, 164) = 3.62, P = .004$ ]. A Tukey *post-hoc* test revealed that F1 of I\_I (i:) vowel in Urdu is significantly different from Sindhi I\_I [ $P = .039$ ], Punjabi I\_I vowel is significantly different from Sindhi [ $P = .017$ ] I\_I vowel. Sindhi I\_I vowel is statistically significantly different from Balochi [ $P = .011$ ] I\_I vowel. There was statistically significant difference among the six language groups as determined by one way ANOVA [ $F(5, 164) = 3.011, P = .013$ ]. A Tukey *post-hoc* test revealed that F2 of I\_I (i:) vowel. Sindhi I\_I vowel is significantly different from Balochi [ $P = .027$ ] and Pashto [ $P = .017$ ] I\_I vowels (for details see APPENDIX E).

The analysis shows that F1, F2 values of I\_I vowels among all these six accents are different from each other i.e. I\_I vowel uttered by Urdu and Punjabi speakers are significantly different from I\_I vowel uttered by Sindhi speakers. I\_I vowels uttered by

Sindhi speakers are significantly different from I\_I vowels uttered by Balochi and Pashto speakers.

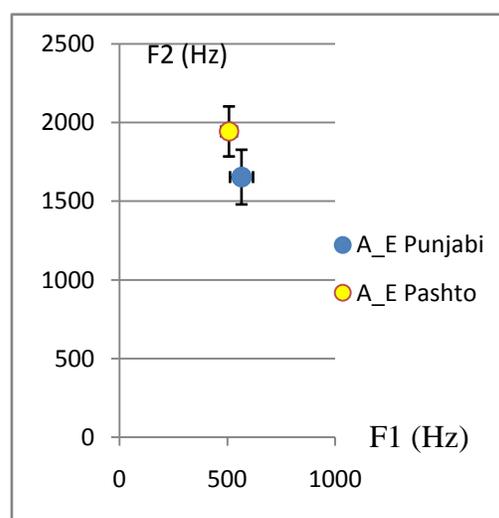

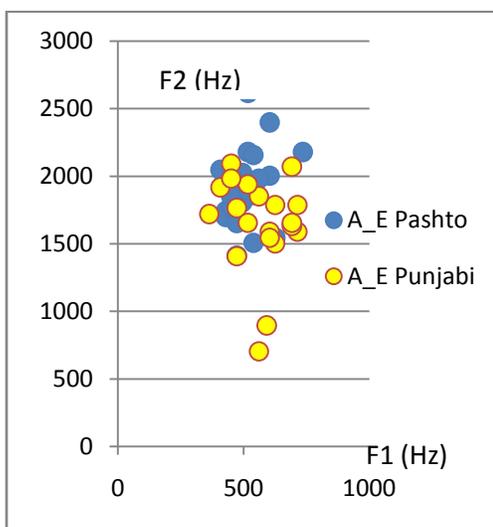

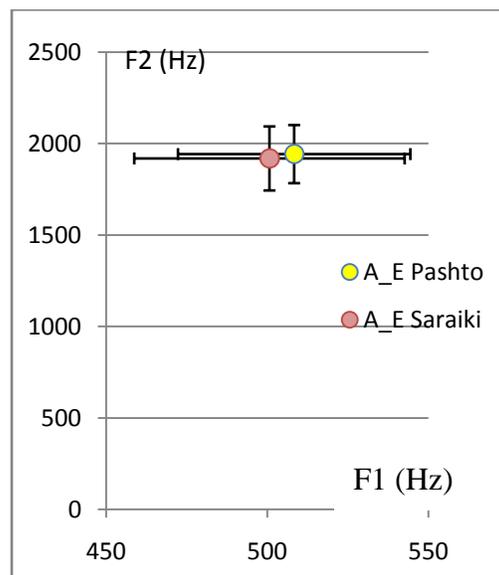

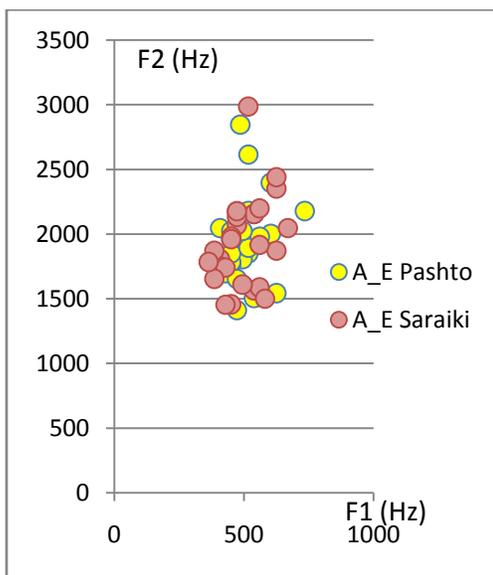

#### 4.2. Acoustic Analysis of A\_E (æ:) Vowels

/æ:/ vowel is produced when the tongue moves backward by increasing the gap between lower and upper jaws but lips are in more spread posture than /i:/ vowel (Skandera & Burleigh, 2005). In Urdu, /æ:/ vowel has slightly lower F1 value and higher F2 value (700-1700 Hz) than /a:/ vowel.

The recorded data was processed in PRAAT software. The data is based on F1, F2 values of /æ:/ vowels. For the understanding of the data variation the cluster graphs have been made which show the similar as well as contrastive behavior of different vowels uttered by the speakers of six languages. These graphical representations show that frequencies of vowels vary from each other but some pair wise comparisons show more contrastive behavior than the other. Few of them are elaborated here;

### Pair wise Comparison of A\_E Vowels Uttered by Different Language Speakers

The pair wise comparison shows rate of variation in the formant frequencies (F1, F2) among the utterances from the speakers of the different languages. The pair wise comparison of A\_E vowel uttered by Pashto and Saraiki speakers shows less variation than A\_E vowel uttered by Punjabi and Pashto speakers.

Figure 26: shows the group wise comparison of the mean and standard deviation of (the long vowel /æ:/) A\_E vowel uttered by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages. This group wise comparison shows that the formant frequency values of A\_E vowel uttered by the Balochi speakers are equally different from the formant frequencies of A\_E vowel uttered by the speakers of Urdu, Punjabi, Sindhi, Saraiki and Pashto. The formant frequencies of A\_E vowel uttered by Punjabi speakers are drastically different from Sindhi, Pashto, Saraiki and Balochi but less drastically variant from the utterances of Urdu speakers.

### Group wise Comparison of A\_A Vowels

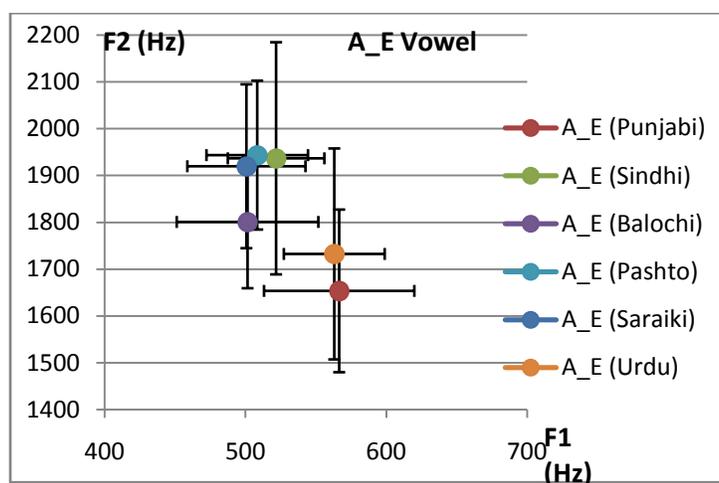

Figure 26: Mean & St. Deviation of /æ:/ Vowels

ANOVA test has been run for the verification of the results.

### Statistical Analysis of A\_E (æ:) Vowel

Table 40: *Difference among /æ:/ vowels*

<b>Accents</b>	<b>F1</b>
<b>Punjabi-Pashto</b>	0.056

One way ANOVA test was run to determine, if there was any significant difference in A\_E vowel accent (F1, F2) among the six groups of languages. There were no outliers and the data was normally distributed for each group and assessed by the Tukey *post-hoc* test [ $p < .05$ ]. There was statistically significant difference among groups as determined by one way ANOVA [ $F(5, 116) = 2.669, P = .025$ ]. A Tukey *post-hoc* test revealed that F1 of A\_E (æ:) vowel in Punjabi is significantly different from Pashto [ $P = .056$ ] A\_E vowels (for details see APPENDIX E). The result shows that there is no significant difference among other formant frequencies of the vowels except Punjabi and Pashto. So, A\_E vowel in Urdu and Punjabi accents are not significantly different from each other. But A\_E vowels uttered by the Punjabi speakers are significantly different from the A\_E vowel uttered by Pashto speakers.

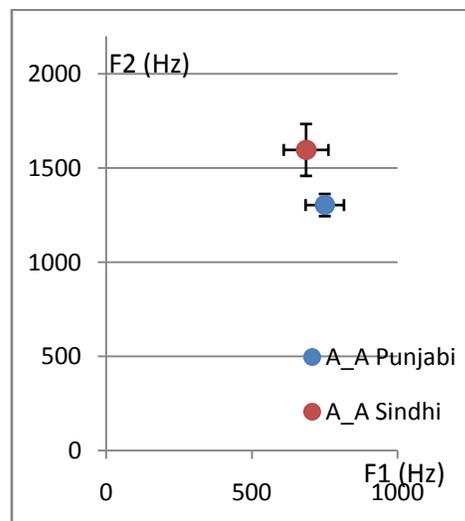

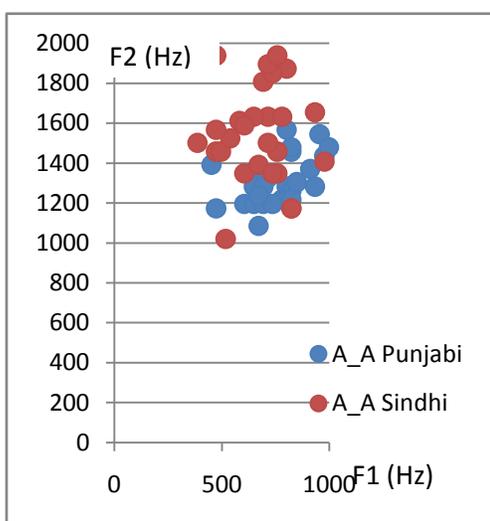

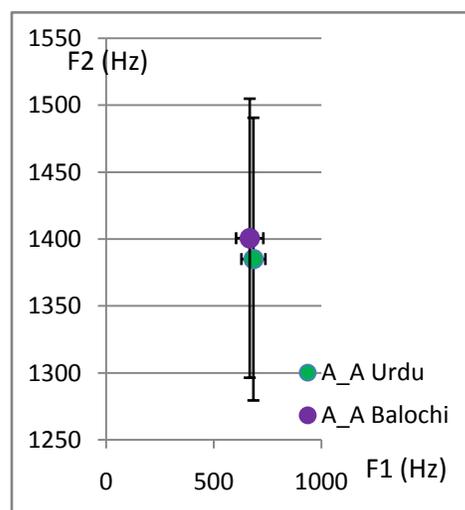

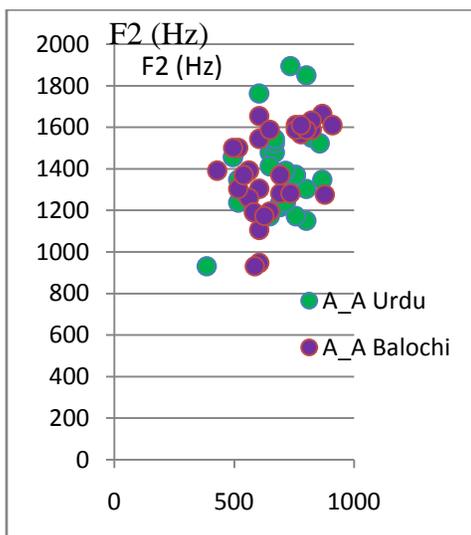

### 4.3. Acoustic Analysis of A\_A (a:) Vowel

/a:/ vowel is produced when the tongue moves backward by maximizing the gap between lower and upper jaws but lips remain wide open for articulation (Skandera & Burleigh, 2005). In Urdu language, /a:/ vowel has upper F1 and lower F2 values (700-1100 Hz) than /i:/ vowel.

The recorded data was processed in PRAAT software. The data is based on the F1, F2 values of /a:/ vowels. For the understanding of the data variation cluster graphs have been made which show the similar as well as contrastive behavior of different vowels uttered by the speakers of six languages. These graphical representations show that frequencies of vowels vary from each other but some pair wise comparisons show more contrastive behavior than the other. Few of them are elaborated here;

### Pair wise Comparison of A\_A Vowels Uttered by Different Language Speakers

The pair wise comparison shows rate of variation of the formant frequencies (F1, F2) among the utterances from the speakers of the different languages. The pair wise comparison of A\_A vowel uttered by Urdu and Balochi speakers shows less variation than the A\_A vowel uttered by Punjabi and Sindhi speakers.

Figure 27: shows the group wise comparison of the mean and standard deviation of (the long vowel /a:/) A\_A vowels uttered by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages. This group wise comparison shows that the formant frequency values of A\_A vowel uttered by Punjabi speakers are drastically different from the formant frequencies of A\_A vowels uttered by the speakers of Sindhi language. A\_A vowel uttered by Punjabi speakers shows deviation from A\_A vowels uttered by the speakers of Urdu, Balochi, Pashto and Saraiki languages. A\_A vowels uttered by the speakers of Sindhi language are totally different from A\_A vowel uttered by the speakers of Urdu, Punjabi, Balochi, Pashto and Saraiki languages.

	Pashto	1.000		Pashto	.988		

One way ANOVA test was run to determine, if there was any significant difference in A\_A vowel accent (F1, F2) among the six groups of language. There were no outliers and the data was normally distributed for each group and assessed by the Tukey *post hoc* test [ $P < .05$ ]. There was statistically significant difference among groups as determined by one way ANOVA [ $F(5, 174) = 3.799, P = .003$ ]. A Tukey *post-hoc* test revealed that F1 of A\_A (a:) vowel in Punjabi is significantly different from Pashto accent [ $P = .002$ ]. There was statistically significant difference among groups as determined by one way ANOVA [ $F(5, 174) = 6.244, P = .000$ ]. A Tukey *post-hoc* test revealed that F2 of A\_A (a:) vowel uttered by the speakers of Urdu is significantly different from the speakers of Sindhi language [ $P = .003$ ], A\_A vowels uttered by the speakers of Punjabi language are significantly different from the speakers of Sindhi language [ $P = .000$ ], A\_A vowels uttered by the speakers of Sindhi language are significantly different from the speakers of Pashto [ $P = .000$ ] and Saraiki [ $P = .005$ ]. For details see APPENDIX E

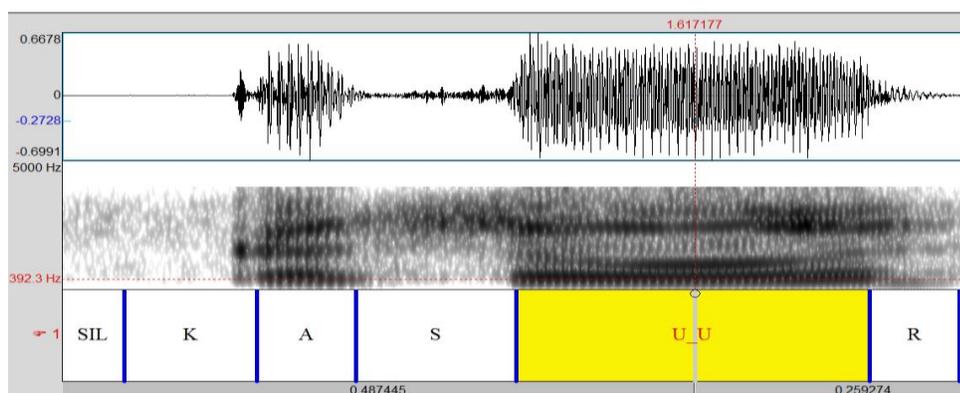

Table 41: *Difference among /a:/ Vowels*

<b>Accents</b>	<b>F1</b>	<b>F2</b>
<b>Punjabi-Pashto</b>	0.002	---
<b>Urdu- Sindhi</b>	---	0.003
<b>Punjabi-Sindhi</b>	---	0.000
<b>Sindhi-Pashto</b>	---	0.000
<b>Sindhi-Saraiki</b>	---	0.005

The result shows after analyzing F1, F2 values of A\_A vowels among the utterances of the speakers of all six major languages. A\_A vowels uttered by the speakers of Sindhi language are significantly different from Urdu, Punjabi, Pashto and Saraiki A\_A vowels. A\_A vowels uttered by the Punjabi speakers are also different from Pashto A\_A vowel.

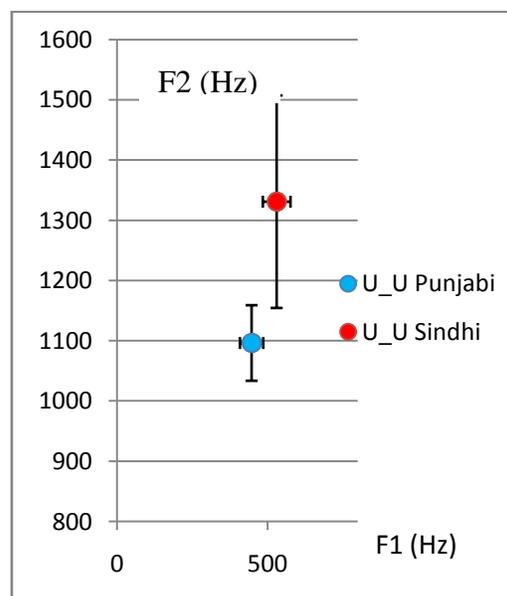

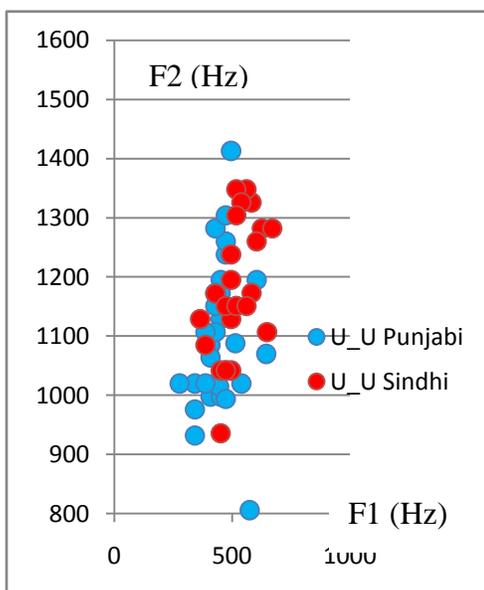

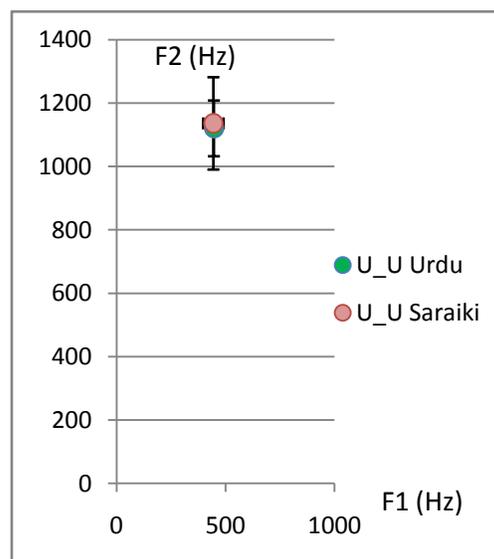

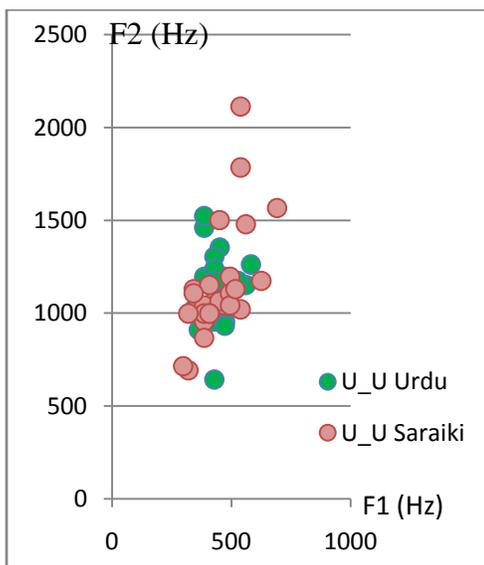

#### 4.4. Acoustic Analysis of U\_U (u:) Vowel

/u:/ vowel is produced when the tongue pushes forward by minimizing the gap between the tongue body and the palate but lips are close and in rounded posture (Skandera & Burleigh, 2005). In Urdu language, /u:/ vowel has slightly up F1 and lower F2 values (300-700 Hz) than /i:/ vowel.

The recorded data was processed by PRAAT software. The data is based on the F1, F2 values of /u:/ vowels. For the understanding of the data variation cluster graphs have been made which show the similar as well as contrastive behavior of the different vowels uttered by the speakers of six languages. These graphical representations show that frequencies of vowels vary from each other but some pair wise comparisons show more contrastive behavior than the other. Few of them are elaborated here;

### Pair wise Comparison of U\_U Vowels Uttered by Different Language Speakers

The pair wise comparison shows rate of variation of the formant frequencies (F1, F2) among the utterances from the speakers of the different languages. The pair wise comparison of U\_U vowels uttered by Urdu and Saraiki speakers show less variation than the U\_U vowels uttered by Punjabi and Sindhi speakers.

### Group wise Comparison of U\_U Vowels

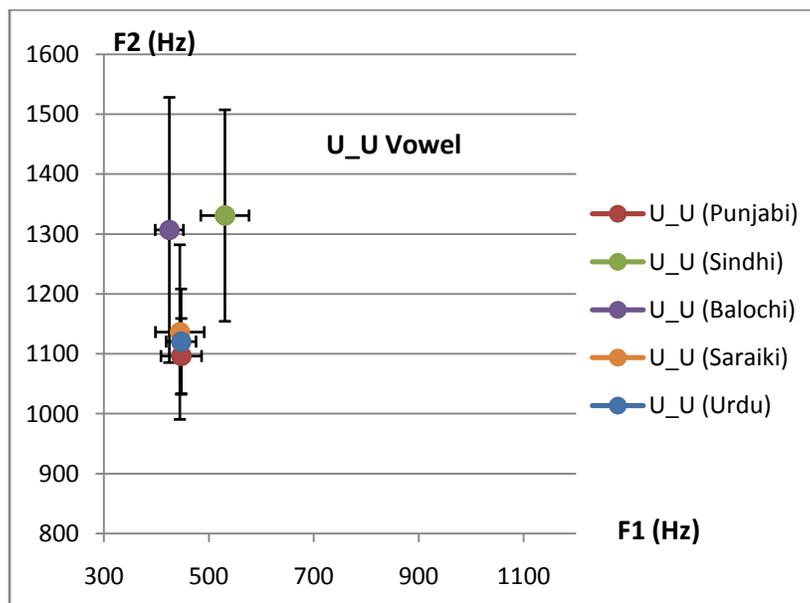

Figure 28: Mean & St. Deviation of /u:/ Vowels

Figure 28: shows the group wise comparison of the mean and standard deviation of (the long vowel /u:/) U\_U vowels uttered by the speakers of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages. This group wise comparison shows that the formant frequency values of U\_U vowel uttered by the Balochi and Sindhi speakers are drastically different from the formant frequencies of I\_I vowel uttered by the speakers of Urdu, Punjabi.

ANOVA test has been run for the verification of the results.

One way ANOVA test was run to determine, if there was any significant difference in U\_U vowel (F1, F2) uttered by the speakers of the six languages. There were no outliers and the data was normally distributed for each group and assessed by the Tukey *post-hoc* test [ $p < .05$ ]. There is statistically significant difference among five groups as determined by one way ANOVA [ $F(5, 167) = 8.53, P = .000$ ]. A Tukey *post-hoc* test revealed that F1 of U\_U (u:) vowel uttered by the speakers of Urdu language are significantly different from Sindhi U\_U [ $P = .000$ ]. U\_U vowel uttered by the speakers of Punjabi language are significantly different from U\_U vowels uttered by Sindhi speakers [ $P = .000$ ]. U\_U vowels uttered by the speakers of Sindhi language are significantly different from the vowels uttered by Balochi [ $P = .000$ ] and Saraiki [ $P = .000$ ] speakers (For details see APPENDIX E).

Table 42: *Difference among /u:/ Vowels*

<b>Accents</b>	<b>F1</b>
<b>Urdu-Sindhi</b>	.000
<b>Punjabi-Sindhi</b>	.000
<b>Sindhi-Balochi</b>	.000
<b>Sindhi-Saraiki</b>	.000

Pashto U\_U vowel has not been used in this comparison. Because Pashto U\_U vowel is pronounced with more lips rounding and has become the cause of the lowering F3 formants. Therefore, F3 merged with the F2 and it was difficult to find and measure the F2 values of Pashto /u:/ vowels.

The result shows after analyzing F1, F2 values of U\_U vowels uttered by the speakers of Sindhi language is significantly different from the formant values of U\_U vowels pronounced by the speakers of Urdu, Punjabi, Balochi and Saraiki U\_U languages.

After calculating, the mean values of formants (F1, F2) and standard deviation of all these corner vowels. These values have been compared with each other for finding the difference among them. Then the four corner vowels have been mapped with the help of these values mentioned in the table 44.

Table 44: *Mean and Standard Deviation of F1, F2 among Six Languages*

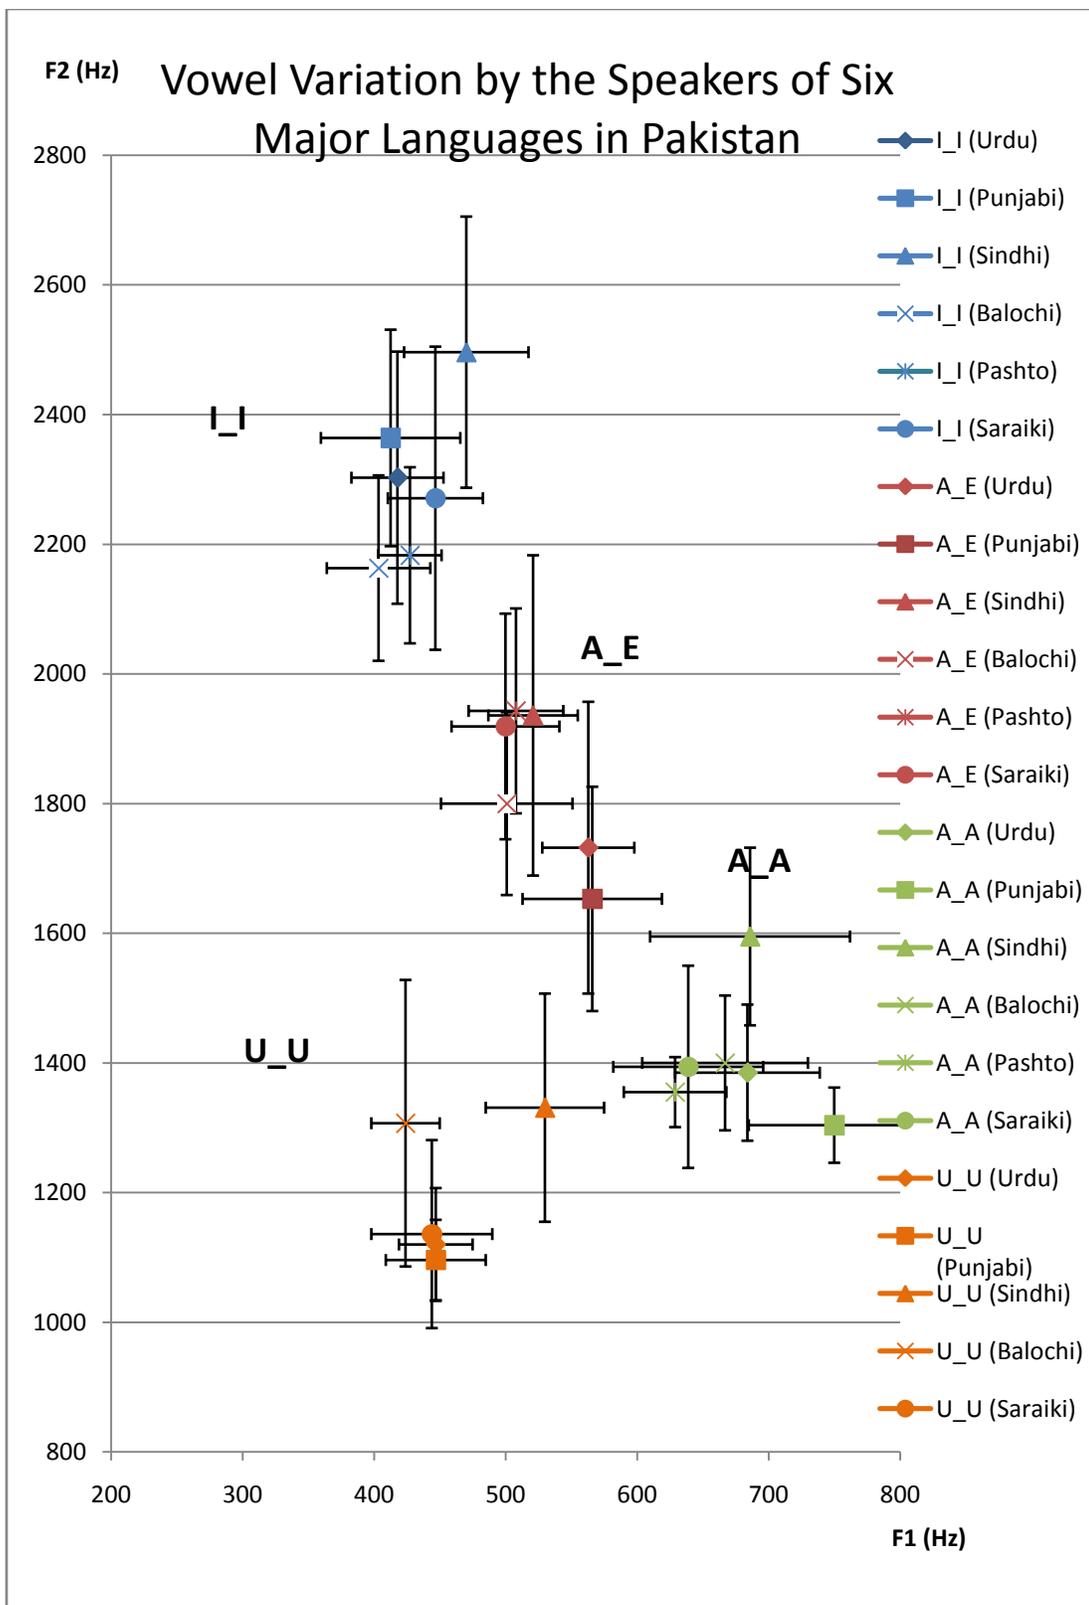

Figure 29: Mean &Std. Deviation of F1, F2 among Corner Vowels by the Speakers of Six Languages

All the six languages; Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki have also been compared pair wise for finding out vowel variations. Accent variations among all these six accents have been calculated by knowing the significant gaps among the values of F1, F2 or both of them because the acoustic properties of a vowel is dependent on first two formants (Reetz & Jongman, 2008).

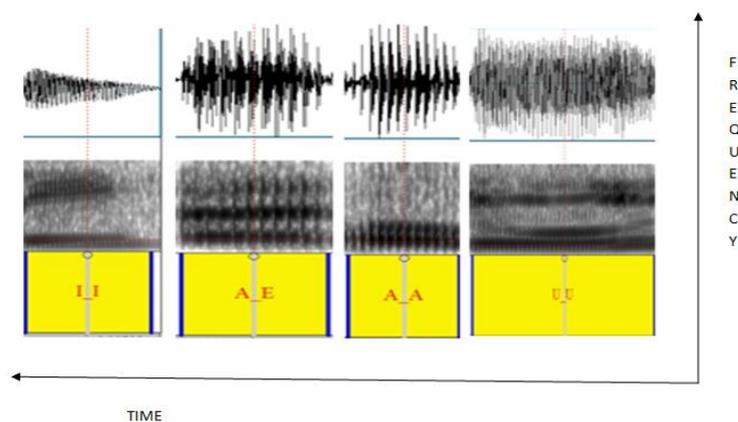

Figure 29: Comparison of Urdu Corner Vowels

Balochi					u:	
Pashto						u:
Saraiki						

Red Color for difference based on F1 of vowels

Green Color for difference based on F2 of vowels

Grey shaded area shows repetition of comparisons among languages

It has been cleared by the analysis that vowels are produced with the loud acoustic signals in all six accents of Urdu i.e. Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. First two formant frequencies are the primary acoustic properties of the vowels in all six accents. The dark bands represent the formant frequencies in order to reflect the resonance in vocal tract. Formant frequencies of vowels are directly affected by the *positions of articulators* in the oral tract among all accents and the same formant frequencies can be generated with the different articulatory positions. Among the utterances of all six language speakers, the *locations of formant* frequencies show the clear difference in each corner vowel. For example, in the utterances of all six languages, /i:/ vowel has first formant frequency around 200-300 Hz and second frequency around 2200-2400 Hz (for the formant values of other vowels see figure 44). In the utterances of the speakers of all the six languages, *Vowel height* is also inversely related with the first formant i.e. the higher the vowel lower will be the F1 value. This is applicable for both front and back vowels. For example, in all six accents, vowels of comparable height /i:/ and /u:/ show comparable first formant frequencies and on the other side /æ:/ and /a:/ show comparable similarity in first formant frequencies. *Vowel backness* is reflected in the second formant frequency (Reetz & Jongman, 2008). Larger gap between F2 and F1 reflects the front vowels i.e. /i:/, /æ:/ and smaller gap reflects the back vowels i.e. /a:/ and /u:/ among the utterances by the speakers of all six languages in Pakistan. *Lips rounding* lower all the formants of vowels. Among all the utterances by the speakers of six languages, *duration* also plays an important role in vowel's identity i.e. long /i:/ differs from short /i/ in terms of duration of the dark bands in spectrum. In all the utterances by the speakers (of Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki languages); the

formant frequencies of the vowels are *stable in the middle of the vowel* because at this point vowel is away from the influence of the surrounding consonantal segments (Reetz & Jongman, 2008). This is clear that a vowel has different acoustic properties which are responsible for providing unique information about the particular identity of a specific accent.

After analyzing the data, it is concluded;

- The formant frequencies of the vowels uttered by the speakers of Urdu and Punjabi are not identical but similar to each other.
- The formant frequencies of the vowels uttered by the speakers of Urdu are different from the vowel formant values (utterances) by the speakers of Sindhi, Pashto and Saraiki languages.
- The formant frequencies of the vowels uttered by the speakers of Punjabi language are different from the utterances Sindhi, Balochi, Pashto and Saraiki accents.
- Pair wise comparison of the utterances by the speakers of all six languages shows;
  - The formant frequencies of the vowels uttered by the speakers of Sindhi accent are different from Urdu, Punjabi, Balochi, Pashto and Saraiki speakers' utterances.
  - The formant frequencies of the vowels uttered by the speakers of Balochi accent are different from Urdu, Punjabi, Sindhi, Pashto and Saraiki languages.

- The formant frequencies of the vowels uttered by the speakers of Pashto are different from the formant frequencies (utterances) Urdu, Punjabi, Sindhi, Balochi and Saraiki language speakers.
- The formant frequencies of the vowels uttered by the speakers of Saraiki are also different from the formant values (utterances) of Urdu, Punjabi, Sindhi, Balochi and Pashto language speakers.

## CHAPTER 5

### CONCLUSION

The present research has been conducted for finding out the accent variation in Pakistani Urdu language. Although Urdu is an official language but Pakistan is a multilingual country where majority of speakers having different first languages. So we have analyzed the affect of the accents of majorly spoken languages on Urdu. Data has been collected by using the medium of telephone or mobile phone. Students of different Pakistani universities have been volunteered for recordings of speech corpus (the list of district names). The quantitative methodology has been adopted for finding out accent variations by means of measuring vowel frequencies.

The present research is based on the acoustic analysis of the spectrograms of the words and their segments. As, this is the first attempt for finding out the accent variation therefore, only deals with the analysis of the corner vowels only. Four corner vowels have been analyzed acoustically by measuring first two formant frequencies F1 and F2 after taking the spectral slices. The formant frequencies of Urdu vowels have been extracted from the wave files uttered by the speakers of six majorly spoken languages; Urdu, Punjabi, Sindhi, Balochi, Pashto and Saraiki. The first two frequencies (F1, F2) have been measured in Hertz of the “corner vowels” /i:/, /æ:/, /a:/ and /u:/ vowels uttered by the speakers of all the six languages. Mean values of formants have been calculated from the utterances of the speakers of each language then compared pair wise and group wise.

The acoustic phonetic analysis of the corner vowels has shown the idiosyncratic behavior of /i:/, /æ:/, /a:/ and /u:/ vowels among utterances by the speakers of six languages. The analysis also verified that the formant frequencies (F1, F2) of the vowels uttered by the speakers of all languages are different from each other. Even the formant frequencies of Urdu and Punjabi speakers' utterances are similar but not identical to each other. So, we can say that the vowels uttered by Urdu and Punjabi speakers can map on each other but are different from Sindhi, Balochi, Pashto and Saraiki speakers' vowel utterances. The vowels uttered by the speakers of Sindhi, Balochi, Pashto and Saraiki languages are not only different from each other but also show difference from Urdu and Punjabi languages. This study also confirms that accent variation depends on the multilingualism of the people in Pakistan. The other reason is the fact that Urdu is the second or third language to almost all Pakistanis (Rehman, 2002) and the reason of variations among these accents is the affect and influence of the native languages of Pakistani people.

### **5.1. Recommendations and Future Directions**

The present study gives the sufficient information about the vowel variation with reference to formant values. The experimentation shows that two dimensional features F1 and F2 are not enough to identify the different accents spoken in different geographical regions of Pakistan. Therefore it is essential to find out more dimensions of speech data;

- The acoustic analysis of Urdu consonantal inventory and the other vowels are still in need to study in future.

- Supra segmental features of phonetic inventory can be analyzed acoustically by measuring the duration, stress, pitch, intensity, intonation and loudness in all six accents of Pakistani Urdu.

## **APPENDIX A**

### **Consent Form**

Dear Respondent!

I am Mahwish Farooq, M. Phil scholar in University of Management and Technology. I am doing research on the topic “An Acoustic Phonetic Study of Six Accents of Urdu in Pakistan” I want to have your consent in my research, I assure you for confidentiality of the information given by you. This information will be used for research purpose only. I would be grateful for your valued contribution.

Thanks in Anticipation

Mahwish Farooq

<b>Sr. no.</b>	<b>Subdivisions</b>	<b>Major Languages</b>	<b>Districts</b>
<b>1</b>	Balochistan	Balochi & 10-12 minor languages are used	30
<b>2</b>	Khyber Pakhtunkhwa	Pashto & Almost 35 minor languages are used	24
<b>3</b>	Punjab	Punjabi & Almost 30 minor languages are used	36
<b>4</b>	Sindh	Sindhi & Almost 31-34 minor languages are used	23
<b>5</b>	Islamabad Capital Territory	Udru, Punjabi, English	1
<b>6</b>	Federally Administered Tribal Areas (FATA)	Pashto, Urdu, Hindko	7 tribal agencies and 6 frontier regions
<b>7</b>	Azad Kashmir	Kashmiri, Urdu, Hindi	10
<b>8</b>	Gilgit–Baltistan	Balti, Burushaski, Chainies, Domaaki, Gojal, Shina, Wakhi, Urdu	7

## APPENDIX C

### Guidelines for Segment Marking

For the purpose of segment labeling we are using the Case Insensitive Speech Assessment Method Phonetic Alphabet (CISAMPA). Since the IPA symbols are difficult to use for our applications, symbols in the Speech Assessment Method Phonetic Alphabet (SAMPA) are matched to the IPA symbols and used for labeling. Some additions to the existing SAMPA symbols have been made.

The following table shows Urdu letters, their corresponding IPA symbols and the CISAMPA.

Urdu Letter	IPA	CISAMPA	Urdu Letter	IPA	CISAMPA	Urdu Letter	IPA	CISAMPA
پ	p	P	خ	x	X	ق	q	Q
پھ	p <sup>h</sup>	P_H	غ	ɣ	G_G	ع	ʔ	Y
ب	b	B	ح، ہ	h	H	ف	f	F
